

# PHYSICS 215A: QUANTUM MECHANICS

IAN LIM  
LAST UPDATED JANUARY 5, 2020

These notes were taken for Physics 215A, *Quantum Mechanics*, as taught by Mukund Rangamani at the University of California, Davis in fall quarter 2019. I live-T<sub>E</sub>Xed them using Overleaf, and as such there may be typos; please send questions, comments, complaints, and corrections to [itlim@ucdavis.edu](mailto:itlim@ucdavis.edu).

Many thanks to Arun Debray for the L<sup>A</sup>T<sub>E</sub>X template for these lecture notes: as of the time of writing, you can find him at <https://web.ma.utexas.edu/users/a.debray/>.

Lecture 1.

## Wednesday, September 25, 2019

**Motivation** The aim of this course is to revisit quantum mechanics in more depth and more mathematical rigor. The official course text is Shankar's *Principles of Quantum Mechanics*, but the lecturer also recommends Weinberg's *Quantum Mechanics*, Sakurai, and Leslie Valentine. To really understand the foundations of quantum mechanics, Dirac's book is also useful.

**Origins of quantum mechanics** One of the original motivations for quantum mechanics was explaining the blackbody spectrum of thermal radiation. The Rayleigh-Jones curve described the small-temperature limit, and Planck later added a correction, exponential damping at high  $T$ . Underlying Planck's model was some suggestion of quantized, discrete energies, and this theory was further developed with Schrödinger's wave mechanics.

Today, there have been many precision tests of quantum mechanics confirming that quantum mechanics is a good model of small-scale phenomena. We'll spend the rest of this lecture discussing the mathematical formalism which makes quantum mechanics possible.

**Mathematical background** From a mathematical perspective, quantum mechanics is basically infinite-dimensional<sup>1</sup> linear algebra. Why should we care about linear algebra? The key idea is this— quantum mechanics obeys a superposition principle. Our theory is linear, so we can construct new solutions by taking linear combinations of existing ones.

To build this theory, we need objects living in a vector space and some operators acting on those vectors. More precisely, we will deal with

- wavefunctions, i.e. states in a Hilbert space
- *calculables*, representing operator expectation values.<sup>2</sup>

**Definition 1.1.** A *linear vector space* is a collection of elements called *vectors*, denoted by kets  $\{|v_i\rangle\}$ , on which two operations are defined:

- Addition,  $+$  :  $|v\rangle, |w\rangle \rightarrow |v\rangle + |w\rangle$ ,
- and scalar multiplication,  $\alpha|v\rangle, \alpha \in \mathbb{C}$ .

These operations satisfy the following properties. For all  $|v_i\rangle, |v_j\rangle \in V, \alpha \in \mathbb{C}$ ,

- $|v_i\rangle + |v_j\rangle \in V$
- $\alpha|v_i\rangle \in V$ .

From these axioms, it follows that all linear combinations (superpositions) of vectors are allowed. That is, for  $|v_i\rangle, |v_j\rangle \in V, \alpha_i, \alpha_j \in \mathbb{C}$ ,

$$\alpha_i|v_i\rangle + \alpha_j|v_j\rangle \in V. \quad (1.2)$$

Using the axioms, we can also prove some useful properties:

- $\exists |0\rangle \in V$  (additive identity) such that  $|v\rangle + |0\rangle = |v\rangle$ .
- For all  $|v\rangle \in V, \exists |-v\rangle \in V$  (additive inverse) such that  $|v\rangle + |-v\rangle = |0\rangle$ .

We will often be sloppy with our notation and denote  $|0\rangle \sim 0$ , so that  $|v\rangle - |v\rangle = 0$ , which is secretly the zero vector.<sup>3</sup>

It would be frustrating if our set of vectors was simply impossible to manage, i.e. if the vectors had no nontrivial relationships between each other.<sup>4</sup> Therefore, we will introduce the following definition.

**Definition 1.3.** A set of vectors  $\{|w_i\rangle\}$  comprises a *linearly independent set* if no nontrivial linear combination of them sums to zero, i.e. if

$$\sum_i \alpha_i |w_i\rangle = 0 \implies \alpha_i = 0. \quad (1.4)$$

**Definition 1.5.** A set of vectors which is not linearly independent (there exists some combination  $\alpha_i$  not all zero such that  $\sum \alpha_i |w_i\rangle = 0$ ) is called linearly dependent.

Linear independence allows us to pick a special *basis set*, which we denote  $\{|e_n\rangle\}$ . This set is chosen such that for *any*  $|v\rangle \in V$ , there exists a decomposition

$$|v\rangle = \sum \alpha_n |e_n\rangle. \quad (1.6)$$

Let's illustrate this with some examples.

**Example 1.7.** The space  $\mathbb{R}^3$  is a (real) vector space, where vectors can be denoted

$$\mathbf{v} = x\hat{e}_x + y\hat{e}_y + z\hat{e}_z. \quad (1.8)$$

<sup>1</sup>Well, finite in spin systems and so on.

<sup>2</sup>We won't get into the details of measurement or observation in this course.

<sup>3</sup>However, we will sometimes indicate a ground (vacuum) state by  $|0\rangle$  instead. The harmonic oscillator (and all of quantum field theory) uses this notation. In that case, the ground state is usually defined to be the state that is annihilated to the true zero vector by the annihilation operators of the theory. That is,  $a|0\rangle = 0$ .

<sup>4</sup>Free fields in abstract algebra are kind of like this.

Equivalently in ket notation we could write

$$|v\rangle = x|e_x\rangle + y|e_y\rangle + z|e_z\rangle. \quad (1.9)$$

This generalizes in the obvious way to  $\mathbb{R}^n$ .

**Example 1.10.** Consider a 1-qubit system, a quantum spin system with two states. A general state is written<sup>5</sup>

$$\alpha|0\rangle + \beta|1\rangle, \quad (1.11)$$

with  $\alpha, \beta \in \mathbb{C}$ . This is a complex vector space, because the coefficients  $\alpha$  and  $\beta$  are complex.

**Example 1.12.** We can define a *discretuum vector space* with a basis set  $\{|n\rangle\}_{n=0,1,2,\dots}$ . A general element can be written as

$$\sum_{n=0}^{\infty} \alpha_n |n\rangle, \quad (1.13)$$

with  $\alpha_n \in \mathbb{C}$ . This is of course the space of states for the harmonic oscillator, or more generally any confining potential.

**Example 1.14.** Consider the space spanned by  $2 \times 2$  matrices with complex entries. In particular, the following set of four matrices forms a basis for this space:<sup>6</sup>

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \mathbb{I}_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \quad (1.15)$$

**Example 1.16.** We could have a continuum vector space which is the space of functions over some domain.<sup>7</sup> In particular, consider the set of Hermite polynomials  $|n\rangle = H_n(x)$ ,  $x \in \mathbb{R}$ , the solutions to the harmonic oscillator potential. This is just a function representation of the solutions. Similarly, the Bessel functions from electromagnetism and spherical harmonics from solving the Laplacian in spherical coordinates also form vector spaces.

The rest of today's discussion centers on how to choose a useful basis.

**Definition 1.17.** If a vector can be written as

$$|v\rangle = \sum_n \alpha_n |e_n\rangle \quad (1.18)$$

with respect to a basis  $\{|e_n\rangle\}$ , we say that the coefficients  $\alpha_n$  are the *components* of  $|v\rangle$  in the basis  $\{|e_n\rangle\}$ .

In a different basis, the components will generally change, but the *vector does not*.<sup>8</sup>

**Normed vector space** It's possible to do linear algebra without an inner product. But we're physicists, so we shall define one.

**Definition 1.19.** An *inner product* is a function of two vectors, denoted in bra-ket notation as

$$(|v\rangle, |w\rangle) = \langle v|w\rangle, \quad (1.20)$$

and which obeys the following properties:

- $\langle v|w\rangle \in \mathbb{C}$
- $\langle v|w\rangle = \langle w|v\rangle^*$
- $\langle v|\alpha_1 w_1 + \alpha_2 w_2\rangle = \alpha_1 \langle v|w_1\rangle + \alpha_2 \langle v|w_2\rangle$
- $\langle v|v\rangle \geq 0$  with  $\langle v|v\rangle = 0 \iff |v\rangle = 0$ .

<sup>5</sup>Some people prefer to denote the basis states as  $|\uparrow\rangle|\downarrow\rangle$  or  $|+\rangle, |-\rangle$ .

<sup>6</sup>These matrices are linearly independent, as one can check by taking a general linear combination. Moreover, the dimension is correct. We need four complex parameters to specify a general element in this space, so it has complex dimension 4. But we've constructed a set of four linearly independent elements, so a linear combination of them will have four complex parameters, which is exactly right to form a basis.

<sup>7</sup>Strictly this is a countable vector space with continuum elements. For a vector space with uncountably infinite basis elements, consider plane waves and a Fourier decomposition.

<sup>8</sup>This is a critical fact in general relativity, where vectors are defined in a tangent bundle.

Inner products generalize the notion of a (scalar) dot product, which measures how parallel two vectors are to one another.

**Definition 1.21.** We can then define the *norm* of a vector as

$$||v|| = \sqrt{\langle v|v \rangle}. \quad (1.22)$$

**Exercise 1.23.** Show that the inner product is antilinear in the first argument, i.e.

$$\langle \alpha_1 v_1 + \alpha_2 v_2 | w \rangle = \alpha_1^* \langle v_1 | w \rangle + \alpha_2^* \langle v_2 | w \rangle. \quad (1.24)$$

We can derive some useful properties of an inner product. The inner product must satisfy the *Schwarz inequality*,

$$|\langle w|v \rangle|^2 \leq \langle w|w \rangle \langle v|v \rangle. \quad (1.25)$$

Recall that in  $\mathbb{R}^3$ , this is just the statement that  $\langle w|v \rangle = \mathbf{v} \cdot \mathbf{w} = |\mathbf{v}| |\mathbf{w}| \cos \theta$ . We can prove it by considering the vector

$$|z\rangle = |v\rangle - \frac{\langle w|v \rangle}{||w||^2} |w\rangle \quad (1.26)$$

and using the positivity of the norm of  $|z\rangle$ .

The inner product also satisfies the *triangle inequality*,

$$||v + w|| \leq ||v|| + ||w||. \quad (1.27)$$

A general basis  $\{|e_n\rangle\}$  can be made orthonormal, i.e. chosen/defined so that the elements obey

$$\langle e_n | e_m \rangle = \delta_{nm}. \quad (1.28)$$

This can always be done by the Gram-Schmidt algorithm.<sup>9</sup>

In an orthonormal basis, the inner product between two vectors is very easy to calculate. With  $|v\rangle = \sum \alpha_n |e_n\rangle$ ,  $|w\rangle = \sum \beta_n |e_n\rangle$ , the inner product is given by

$$\langle v | w \rangle = \sum_n \alpha_n^* \beta_n. \quad (1.29)$$

**Dual vector space** We wish to use the inner product to define a *dual vector space*. Strictly we don't need an inner product to do this, but it provides a natural way to do so.<sup>10</sup>

**Definition 1.30.** Given a vector space  $V$ , we define the dual vector space  $V^*$ , whose elements are *linear functionals* on  $V$ . That is, if  $F_w \in V^*$ , then

$$F_w : V \rightarrow \mathbb{C} \quad (1.31)$$

such that

$$F_w(\alpha_1 |v_1\rangle + \alpha_2 |v_2\rangle) = \alpha_1 F_w(|v_1\rangle) + \alpha_2 F_w(|v_2\rangle). \quad (1.32)$$

Moreover, we claim that the dual vector space deserves its name; it is an honest vector space. This is pretty easy to check, i.e. that linear combinations of linear functionals are themselves linear functionals.

For a ket vector  $|v\rangle \in V$ , we can associate a bra vector  $\langle v| \in V^*$ . Given a basis  $\{|e_n\rangle\}$  for  $V$ , we may define a dual basis  $\{\langle e_m|\}$  for  $V^*$ , defined such that

$$\langle e_m | e_n \rangle = \delta_{mn}. \quad (1.33)$$

Note that this immediately implies that any ket vector has a corresponding bra vector in the natural way. That is, we may define an *adjoint operation* such that for

$$|v\rangle = \sum_n \alpha_n |e_n\rangle, \quad (1.34)$$

<sup>9</sup>See my 204A notes for the details.

<sup>10</sup>This generalizes beautifully to curved spacetimes in general relativity. An inner product (metric)  $g_{ab}$  defines a map from two vectors to a scalar,  $g_{ab} : V \times V \rightarrow \mathbb{C}$ , given by  $g_{ab} V^a W^b$ . But it also naturally defines a map from vectors  $V^a$  to dual vectors  $V_b = g_{ab} V^a$ , where the dual vector  $V_b$  is now a map from a single vector to a scalar,  $V_b : V \rightarrow \mathbb{C}$  defined by  $V_b W^b$ . The only complication is that a metric need not be positive semi-definite, so norms can be negative when we measure distances in spacetime. You might know this as the difference between timelike and spacelike separations.

there exists a corresponding bra vector

$$\langle v| = \sum_n \alpha_n^* \langle e_n|. \quad (1.35)$$

In this sense, the vector space  $V$  and its dual vector space  $V^*$  are isomorphic.

We can also write the vectors in a funny way:

$$|v\rangle = \sum_n \langle e_n|v\rangle |e_n\rangle \quad (1.36)$$

and similarly

$$\langle v| = \sum_m \langle v|e_m\rangle \langle e_m|. \quad (1.37)$$

That is, the components of a vector are simply given by its projections onto the basis vectors.

Lecture 2.

**Tuesday, October 1, 2019**

Now that we have defined vectors and vector spaces, let us define linear operators.

**Definition 2.1.** An *operator* is a map  $\mathcal{O} : V \rightarrow V$  such that

$$|v'\rangle = \mathcal{O}|v\rangle. \quad (2.2)$$

Linear operators obey

$$\mathcal{O}(\alpha_1|v_1\rangle + \alpha_2|v_2\rangle) = \alpha_1\mathcal{O}|v_1\rangle + \alpha_2\mathcal{O}|v_2\rangle. \quad (2.3)$$

Operators form an algebra, i.e. addition and multiplication are defined on operators such that

$$(A + B)|v\rangle = A|v\rangle + B|v\rangle \quad (2.4)$$

$$(AB)|v\rangle = A(B|v\rangle). \quad (2.5)$$

Addition is commutative, but multiplication is not—generically,<sup>11</sup>

$$AB \neq BA. \quad (2.6)$$

Multiplication is however associative,

$$A(BC) = (AB)C. \quad (2.7)$$

Linear operators can be thought of as generalizations of matrices. In particular they have *matrix elements* given by  $\langle v|\mathcal{O}|w\rangle$  or in a basis,

$$\langle e_n|\mathcal{O}|e_m\rangle = \mathcal{O}_{nm}. \quad (2.8)$$

If  $\mathcal{O}|v\rangle = |w\rangle$  and  $|v\rangle = \sum_n v_n|e_n\rangle, |w\rangle = \sum_m w_m|e_m\rangle$ , then it follows

$$w_m = \sum_n \mathcal{O}_{mn} v_n. \quad (2.9)$$

**Exercise 2.10.** Check Eq. 2.9 from the definition of the matrix element and inner product.

Sometimes we conflate operators with their matrix elements, but the matrix elements are basis-dependent; the operator is not.

<sup>11</sup>The non-commutativity of operators in quantum mechanics is of course the reason for the Heisenberg uncertainty principle. We'll see this later.

**Adjoint of an operator** Let us now define the adjoint of an operator. Normally we have

$$\langle v|\mathcal{O}|w\rangle = \langle v|(\mathcal{O}|w\rangle), \quad (2.11)$$

but can we construct some operator that allows us to evaluate this as

$$(\langle v|\mathcal{O})|w\rangle? \quad (2.12)$$

**Definition 2.13.** If  $\mathcal{O}|v\rangle = |w\rangle$ , let us define the adjoint  $\mathcal{O}^\dagger$  by

$$\langle v|\mathcal{O}^\dagger = \langle w|. \quad (2.14)$$

From this definition, it follows that since  $\langle z|v\rangle = \langle v|z\rangle^*$ , we have

$$\langle v|\mathcal{O}^\dagger|z\rangle^* = \langle z|\mathcal{O}|v\rangle. \quad (2.15)$$

In terms of matrix elements, we know this is just the conjugate transpose,

$$(\mathcal{O}^\dagger)_{mn} = O_{nm}^*. \quad (2.16)$$

As a matrix,  $\mathcal{O}^\dagger = (\mathcal{O}^*)^T$ .

Notice that the adjoint has the following properties:

- $(\alpha\mathcal{O})^\dagger = \alpha^*\mathcal{O}^\dagger$  for  $\alpha \in \mathbb{C}$
- $(A+B)^\dagger = A^\dagger + B^\dagger$
- $(AB)^\dagger = B^\dagger A^\dagger$ .

**Exercise 2.17.** Check these properties from the definition of the adjoint.

Some examples of operators include the following:

- $\mathbb{I}$ , the identity operator acting as  $\mathbb{I}|v\rangle = |v\rangle$ .
- Over  $\mathbb{C}^2$  spanned by  $\{|1\rangle, |0\rangle\}$ , the Pauli matrices and the identity element are linear operators. In particular they are complete, and obey the commutators

$$[\sigma_i, \sigma_j] = 2i\epsilon_{ijk}\sigma_k \quad (2.18)$$

$$[\sigma_i, \mathbb{I}] = 0. \quad (2.19)$$

In finite dimension, operators are basically matrices. How do we generalize to the infinite-dimensional cases we often see in quantum mechanics?

**Example 2.20.** Consider first the vector space of smooth functions  $\{f(x)\}$  on  $\mathbb{R}$ . We can define operators  $x^m, m \in \mathbb{Z}_{\geq 0}$  which simply multiply these smooth functions,

$$x^m : f(x) \rightarrow x^m f(x). \quad (2.21)$$

**Example 2.22.** The derivative also defines an operator on this vector space. We might define

$$x \frac{\partial}{\partial x} : f(x) \mapsto x f'(x) \quad (2.23)$$

or similarly

$$\frac{\partial}{\partial x} x : f \mapsto \frac{\partial}{\partial x}(x f(x)) = x f' + f \quad (2.24)$$

Sometimes we will write

$$\frac{\partial}{\partial x} x = x \frac{\partial}{\partial x} + 1, \quad (2.25)$$

omitting the function  $f$ .

**Self-adjoint operators and computables** In a sentence, we can describe quantum mechanics as complex matrix linear algebra in infinite dimensions. But let us note that while QM in general is complex, the things we measure must be real. This leads us to introduce the notion of self-adjoint operators.

**Definition 2.26.** A *self-adjoint operator* is an operator satisfying

$$\langle w|\mathcal{O}|v\rangle = \langle v|\mathcal{O}|w\rangle^*. \quad (2.27)$$

In other words,  $\mathcal{O} = \mathcal{O}^\dagger$ , or in terms of matrix elements,  $\mathcal{O}_{nm} = \mathcal{O}_{mn}^*$ .

For most cases, self-adjoint  $\sim$  Hermitian.<sup>12</sup> Self-adjoint operators are nice because their eigenvalues are *real*, meaning that they correspond to observables in our theory.

We'll also use the following definition later, the trace.

**Definition 2.28.** The *trace* of an operator is defined to be

$$\text{Tr}(\mathcal{O}) = \sum_n \langle e_n|\mathcal{O}|e_n\rangle. \quad (2.29)$$

We claim it is independent of basis, and in fact we will prove it on the first homework.

**Eigenspectrum** Just as in the finite-dimensional case, we can talk about the eigenvectors and eigenvalues of operators acting on infinite-dimensional spaces.

**Definition 2.30.** The (nonzero) vector  $|w\rangle$  is an eigenvector of the operator  $\mathcal{O}$  with eigenvalue  $\alpha$  if

$$\mathcal{O}|w\rangle = \alpha|w\rangle, \alpha \in \mathbb{C}. \quad (2.31)$$

Hermitian operators have real eigenvalues, since

$$\mathcal{O}|w\rangle = \alpha|w\rangle \implies \langle w|\mathcal{O}^\dagger = \alpha^*\langle w|. \quad (2.32)$$

Sandwiching with  $\langle w|$  or  $|w\rangle$  as appropriate, we see that

$$\langle w|\mathcal{O}|w\rangle = \alpha||w||^2 \quad (2.33)$$

and

$$\langle w|\mathcal{O}|w\rangle = \langle w|\mathcal{O}^\dagger|w\rangle = \alpha^*||w||^2 \quad (2.34)$$

since  $\mathcal{O} = \mathcal{O}^\dagger$ . Hence

$$\alpha||w||^2 = \alpha^*||w||^2 \implies \alpha = \alpha^*, \quad (2.35)$$

provided that  $|w\rangle$  is not the zero vector. Note that while the eigenvalues are real, the matrix elements need not be real. For instance,  $\sigma_2$  has complex entries in the  $|0\rangle, |1\rangle$  basis but it is nevertheless Hermitian and has real eigenvalues.

**Theorem 2.36.** If  $A$  is self-adjoint (Hermitian) then all eigenvalues are real. Eigenvectors corresponding to distinct (non-degenerate) eigenvalues are orthogonal.

This theorem follows from a simpler lemma:

**Lemma 2.37.** If  $\langle v|A|v\rangle = \langle v|A|v\rangle^*$  for all  $|v\rangle$  then  $A = A^\dagger$ .

That is, if every diagonal matrix element is real, then the matrix is Hermitian.

*Proof.* To prove this lemma, we need to show that the given condition implies

$$\langle v_2|A|v_1\rangle^* = \langle v_1|A|v_2\rangle. \quad (2.38)$$

Define

$$|v\rangle = \alpha_1|v_1\rangle + \alpha_2|v_2\rangle \quad (2.39)$$

for some  $\alpha_1, \alpha_2 \in \mathbb{C}$ . Then

$$\langle v|A|v\rangle = |\alpha_1|^2\langle v_1|A|v_1\rangle + |\alpha_2|^2\langle v_2|A|v_2\rangle + \alpha_1^*\alpha_2\langle v_1|A|v_2\rangle + \alpha_2^*\alpha_1\langle v_2|A|v_1\rangle. \quad (2.40)$$

We can write  $\langle v|A|v\rangle^*$  as well, taking the complex conjugate of the previous expression. That is,

$$\langle v|A|v\rangle^* = |\alpha_1|^2\langle v_1|A|v_1\rangle^* + |\alpha_2|^2\langle v_2|A|v_2\rangle^* + \alpha_1\alpha_2^*\langle v_1|A|v_2\rangle^* + \alpha_2\alpha_1^*\langle v_2|A|v_1\rangle^*. \quad (2.41)$$

<sup>12</sup>See Homework 1 for an example of how this can fail in an infinite-dimensional vector space.

We know that

$$\langle v|A|v\rangle = \langle v|A|v\rangle^* \quad (2.42)$$

for all  $|v\rangle$ , so setting Eqs. (2.40) and (2.41) equal we find that

$$\alpha_1^* \alpha_2 \langle v_1|A|v_2\rangle + \alpha_2^* \alpha_1 \langle v_2|A|v_1\rangle = \alpha_1 \alpha_2^* \langle v_1|A|v_2\rangle^* + \alpha_2 \alpha_1^* \langle v_2|A|v_1\rangle^*. \quad (2.43)$$

This is true for any  $\alpha_1, \alpha_2$ , so let us evaluate it for  $\alpha_1 = \alpha_2 = 1$ . This yields

$$\langle v_1|A|v_2\rangle + \langle v_2|A|v_1\rangle = \langle v_1|A|v_2\rangle^* + \langle v_2|A|v_1\rangle^*. \quad (2.44)$$

We can also make the choice  $\alpha_1 = 1, \alpha_2 = i$  so that

$$i\langle v_1|A|v_2\rangle - i\langle v_2|A|v_1\rangle = -i\langle v_1|A|v_2\rangle^* + i\langle v_2|A|v_1\rangle^*. \quad (2.45)$$

Dividing by  $i$  and adding these equations yields

$$\langle v_2|A|v_1\rangle^* = \langle v_1|A|v_2\rangle \implies A = A^\dagger. \quad (2.46)$$

□

Some quick definitions:

- An *anti-Hermitian* matrix is one obeying  $A^\dagger = -A$ .
- A *unitary* matrix is one satisfying  $UU^\dagger = \mathbb{I}$ . It may be thought of as a complex rotation on vector space.<sup>13</sup>

Lecture 3.

**Thursday, October 3, 2019**

**Spectral theorem** The spectral theorem roughly tells us that the eigenvectors of hermitian matrices will be guaranteed to form a good basis. Before we state the theorem formally, let us discuss the following. Given some Hermitian operator  $\mathcal{Z}$  with eigenspectrum

$$\mathcal{Z}|z_n\rangle = \zeta_n|z_n\rangle. \quad (3.1)$$

Since we are guaranteed completeness<sup>14</sup> it follows that

$$\mathbb{I}|v\rangle = |v\rangle = \sum |z_n\rangle \langle z_n|v\rangle, \quad (3.2)$$

so in fact reading this as an operator equation, since this is true for any  $|v\rangle$ ,

$$\mathbb{I} = \sum_n |z_n\rangle \langle z_n|. \quad (3.3)$$

We call Eqn. 3.3 the *resolution of the identity*, and this is true for any complete basis set.

That is, given  $|v\rangle \in V$  and  $\langle w| \in V^*$ , there is another operation, the *outer product* (denoted  $\otimes$ ), which is a map from  $(V, V^*) \rightarrow V \otimes V^*$ . That is, it allows us to take a column vector and a row vector and combine them to form an operator (a matrix). Thus

$$|v\rangle \langle w| \in V \otimes V^* \quad (3.4)$$

is an operator such that

$$(|v\rangle \langle w|)|z\rangle = \langle w|z\rangle |v\rangle. \quad (3.5)$$

In tensor notation, we could write these as contravariant and covariant vectors as  $V^\mu, \omega_\nu$  such that the outer product  $(V\omega)^\mu{}_\nu$  has the correct indices.

We can also define the adjoint operation on operators in this notation,

$$(|v\rangle \langle w|)^\dagger = |w\rangle \langle v|. \quad (3.6)$$

The adjoint operator may be thought of as a map  $V \otimes V^* \rightarrow V^* \otimes V$ .

Consider now

$$\mathcal{P}_n \equiv |z_n\rangle \langle z_n| \quad (3.7)$$

<sup>13</sup>Strictly, unitary matrices also include reflections (operations that don't preserve orientation), but we'll discuss anti-linear operators later.

<sup>14</sup>We haven't shown it yet but suppose there's a vector that cannot be expressed as an eigenvector. We can reason to a contradiction. Probably in Shankar?

the projection operator onto  $|z_n\rangle$ . Naturally,  $\mathcal{P}_n\mathcal{P}_n = \mathcal{P}_n$  for any normalized  $|z_n\rangle$  since

$$\begin{aligned}\mathcal{P}_n|v\rangle &= |z_n\rangle\langle z_n|v\rangle \\ \implies \mathcal{P}_n^2|v\rangle &= |z_n\rangle\langle z_n|z_n\rangle\langle z_n|v\rangle = \mathcal{P}_n|v\rangle \text{ if } \langle z_n|z_n\rangle = 1.\end{aligned}$$

In this notation, we may equivalently write the identity as

$$\mathbb{I} = \sum_n \mathcal{P}_n. \quad (3.8)$$

That is, the identity is the sum of all the projection operators. Moreover,

$$\mathcal{Z} = \sum_n \zeta_n |z_n\rangle\langle z_n| = \sum_n \zeta_n \mathcal{P}_n(\mathcal{Z}), \quad (3.9)$$

where the  $\mathcal{P}_n$  are projecting onto the eigenspectrum of  $\mathcal{Z}$ .

Since this is given, it becomes easy to define functions of operators  $f(\mathcal{Z})$  in terms of their eigenspectrum. Namely,

$$f(\mathcal{Z}) = \sum_n f(\zeta_n) \mathcal{P}_n(\mathcal{Z}) \quad (3.10)$$

Note that an operator cannot have a nontrivial kernel (that is, it cannot have a zero eigenvalue) or else our completeness assumption fails. In addition, some functions have a finite radius of convergence and so the power series is not guaranteed to converge if the eigenvalues are unbounded.<sup>15</sup>

Let us also note that we've been working as though these spaces were finite-dimensional, but there are sometimes complications when we go to infinite dimensions. To every self-adjoint operator we can associate a 1-parameter family of projection operators  $\mathcal{P}(\lambda)$ , parametrized by some  $\lambda \in \mathbb{R}$  such that  $\mathcal{P}(\lambda)$  satisfies

- (i)  $\lambda_1 < \lambda_2 \implies \mathcal{P}(\lambda_1)\mathcal{P}(\lambda_2) = \mathcal{P}(\lambda_2)\mathcal{P}(\lambda_1) = \mathcal{P}(\lambda_1)$ . (That is, we always project onto smaller  $\lambda$ .)
- (ii) If  $\epsilon > 0$  then  $\mathcal{P}(\lambda + \epsilon)|v\rangle \rightarrow \mathcal{P}(\lambda)|v\rangle$  as  $\epsilon \rightarrow 0$ . (In a sense this family varies continuously.)
- (iii)  $\mathcal{P}(\lambda)|v\rangle \rightarrow 0$  as  $\lambda \rightarrow -\infty$ .
- (iv)  $\mathcal{P}(\lambda)|v\rangle \rightarrow |v\rangle$  as  $\lambda \rightarrow \infty$ .
- (v)  $\int_{-\infty}^{\infty} \lambda d\mathcal{P}(\lambda) = \mathcal{Z}$ .

**Discrete spectrum** Let's examine these assumptions in the discrete case.

$$\mathcal{P}(\lambda) = \sum_n \Theta(\lambda - \zeta_n) \mathcal{P}_n(\mathcal{Z}), \quad (3.11)$$

where

$$\Theta(x) = \begin{cases} 1 & x > 0 \\ 0 & x \leq 0 \end{cases} \quad (3.12)$$

is the Heaviside step function. In the degenerate case we can project onto the corresponding subspace.

To put this in physics language, we can project onto energy eigenspaces. That is,  $\lambda$  lets us take sums of the projection operators up to some energy eigenstate of our choice. As  $\lambda \rightarrow -\infty$  we're looking at energies below the ground state, so there are no states to project on; as  $\lambda \rightarrow +\infty$  we get all the energies and hence get back the original operator  $\mathcal{Z}$ .

**Continuous spectrum** Let's consider a concrete example. For the position operator  $X$ , which we define as acting on a function  $f(x)$  by

$$Xf(x) = xf(x), \quad (3.13)$$

we could try to solve the eigenvalue equation

$$Xf(x) = \zeta f(x). \quad (3.14)$$

We might be tempted to write the eigenfunctions as delta functions,  $\delta(x - \zeta)$ . But this would be a serious error, since the delta function is really a distribution in the space of linear functionals, and ought to live under integrals. That is,

$$\int_{-\infty}^{\infty} dx \delta(x) f(x) = f(0) \quad (3.15)$$

<sup>15</sup>See Shankar 1.9.1.

is the statement that the delta function should be thought of as only being meaningful when under an integral and paired with a function; it is more like a dual vector, since it takes a function and gives back a number.

Note that from the delta function we can also write other derivative expressions like

$$\delta'(x) : f(x) \rightarrow \mathbb{R}, \quad (3.16)$$

another functional such that

$$\begin{aligned} \delta'[f(x)] &= \int_{-\infty}^{\infty} dx \delta'(x) f(x) \\ &= - \int_{-\infty}^{\infty} dx \delta(x) f'(x) + (\text{boundary term} \rightarrow 0) \\ &= -f'(0). \end{aligned}$$

Given appropriate smoothness of  $f(x)$ , anyway.

To generalize our one-parameter family of projection operators to the continuous case, we can write the projection operators for the position operator  $X$  as

$$\mathcal{P}_X(\lambda)f(x) = \Theta(\lambda - x)f(x). \quad (3.17)$$

That is, we may project onto  $x$  up to  $x = \lambda$ . For notice that

$$\left[ \int_{-\infty}^{\infty} \lambda d\mathcal{P}_X(\lambda) \right] f(x) = \int_{-\infty}^{\infty} \lambda \delta(\lambda - x) d\lambda f(x) = xf(x). \quad (3.18)$$

Hence by (v) above we see that

$$X = \int_{-\infty}^{\infty} \lambda d\mathcal{P}_X(\lambda). \quad (3.19)$$

**Theorem 3.20.** *If  $\mathcal{A}, \mathcal{B}$  are mutually commuting, self-adjoint operators, each with a complete set of eigenvalues, then  $\exists$  a complete orthonormal set of eigenvectors for both  $\mathcal{A}$  and  $\mathcal{B}$  simultaneously.*

Since we are guaranteed this, the name of the game is to find the maximal set of commuting operators.<sup>16</sup> If we find a complete set of commuting operators, then we can not only simultaneously diagonalize all of them, but any other operator that commutes with the given set also has the same eigenbasis.

In a sense, this is much like how we look for conserved quantities in classical mechanics to avoid solving second-order equations. We'll be particularly interested in operators that commute with the Hamiltonian, since energy eigenstates will coincide with eigenstates of those operators.

Lecture 4.

**Tuesday, October 7, 2019**

Today we will introduce the postulates of QM. They are as follows:

- I. The state of a system is described by a *ray*<sup>17</sup> in Hilbert space.<sup>18</sup>
- II. States evolve by unitary evolution,

$$|\psi(t)\rangle = U(t; t_0)|\psi(t_0)\rangle, \quad (4.1)$$

such that  $U^\dagger U = \mathbb{I}$ .<sup>19</sup>

- III. Physical observables<sup>20</sup> correspond to expectation values of linear Hermitian operators which naturally act on states in Hilbert space. That is, for  $\mathcal{A} = \mathcal{A}^\dagger$ , we have the expectation value  $\langle \psi | \mathcal{A} | \psi \rangle$ .

<sup>16</sup>Like we did with angular momentum, for instance, in finding  $J^2$  and  $J_z$ .

<sup>17</sup>That is, a vector defined up to normalization. Two vectors that differ only by normalization should be considered as representing the same physical state.

<sup>18</sup>For our purposes, a Hilbert space is a complex vector space.

<sup>19</sup>Intuitively, so long as time evolution is unitary, states just evolve by complex rotations in Hilbert space. Norms and in particular probabilities are therefore left unchanged by unitary evolution.

<sup>20</sup>That is, observables of closed quantum systems where the observer is *not part of the system*. In Mukund's words, we deal with a "meta-observer theory" where the observer can make measurements on a quantum system. There are attempts (cf. Everettian "many-worlds" QM) to describe the observer as part of the system, but this leads to lots of confusion.

IV. *The Born rule.* A measurement of a physical observable  $\mathcal{A}$  yields exactly one of its eigenvalues  $\lambda$  with probability  $p(\lambda)$  given by

$$\begin{aligned} p(\lambda) &= \langle \psi | \mathcal{P}_\lambda(\mathcal{A}) | \psi \rangle \\ &= \langle \psi | a_\lambda \rangle \langle a_\lambda | \psi \rangle \\ &= ||\langle a_\lambda | \psi \rangle||^2 \end{aligned}$$

where  $\mathcal{P}_\lambda(\mathcal{A})$  is the projection operator onto  $|a_\lambda\rangle$ , the eigenstate with eigenvalue  $\lambda$ , and we recall that  $\mathcal{A}$  has a spectral decomposition  $\mathcal{A} = \sum \lambda |a_\lambda\rangle \langle a_\lambda|$ .

There are different interpretations of measurement in quantum mechanics. Pragmatically speaking, they should all give the same predictions so it doesn't really matter for computations<sup>21</sup> and we will present one of the common interpretations, the *Copenhagen interpretation*. In the Copenhagen interpretation, measurement projects the state vector  $|\psi\rangle$  onto one of the eigenstates of the operator being measured.<sup>22</sup> This is what we might call "collapse of the wavefunction." Notice that

$$\mathcal{A}|\psi\rangle = \sum_\lambda \lambda |a_\lambda\rangle \langle a_\lambda | \psi \rangle, \quad (4.2)$$

where the final inner product is the projection of the original state  $|\psi\rangle$  onto the eigenstate  $\langle a_\lambda|$ , and represents a probability amplitude (namely, its modulus squared represents the probability of measuring  $\lambda$ ).

**Evolution in Hilbert space** By our postulate, time evolution is governed by unitary operators.

**Theorem 4.3** (Wigner). *Any mapping of a complex vector space onto itself that preserves the inner product is implemented either by*

- i) *a unitary operator (linear transformation) or*
- ii) *an anti-unitary operator (anti-linear).*

That is, in case i) we have  $U(\alpha|\psi\rangle) = \alpha U|\psi\rangle$ ,  $\alpha \in \mathbb{C}$ , whereas for an anti-linear operator in ii) we have  $U(\alpha|\psi\rangle) = \alpha^* U|\psi\rangle$ . Most operators in physics are unitary apart from one famous example, which is time reversal.<sup>23</sup>

What Wigner's theorem guarantees us is that every symmetry of Hilbert space can be implemented by a unitary operator or an anti-unitary operator. The state evolution is therefore given by the (unitary) time translation operator, which is in turn generated by the Hamiltonian.<sup>24</sup>

Let us now revisit the notion of expectation values, considering the VEV (traditionally "Vacuum Expectation Value") of an operator:

**Definition 4.4.** The *expectation value* of an operator  $\mathcal{A}$  in a state  $|\psi\rangle$  is given by

$$\langle \mathcal{A} \rangle = \langle \psi | \mathcal{A} | \psi \rangle \quad (4.5)$$

$$= \sum \lambda \langle \psi | a_\lambda \rangle \langle a_\lambda | \psi \rangle. \quad (4.6)$$

We may also talk about the uncertainty (basically the standard deviation) of an operator.

**Definition 4.7.** The uncertainty of an operator  $\mathcal{A}$  is given in terms of expectation values:

$$\Delta \mathcal{A} = \sqrt{\langle (\mathcal{A} - \langle \mathcal{A} \rangle \mathbb{I})^2 \rangle}. \quad (4.8)$$

This is a quantum generalization of the standard deviation from ordinary statistics— we want to know the root mean squared deviation from the mean value  $\langle \mathcal{A} \rangle$ .

<sup>21</sup>But see J.S. Bell, *Speakable and Unsayable in Quantum Mechanics* for more on the philosophy of QM.

<sup>22</sup>The counterpoint to this is the Everettian picture. According to Copenhagen, a measurement is a lossy operation, where we lose information upon making a measurement. In many-worlds, the wavefunction instead branches upon making a measurement. If you like, we discover which branch of the wavefunction we were really on, since we are part of the quantum system.

<sup>23</sup>This has to do with the  $i$  in the Schrödinger equation. Most anti-unitary operators one encounters in QM are related to time reversal in some way. Moreover the fact that the operator is anti-unitary suggests that in QM and even in QFT, there is a special direction for time.

<sup>24</sup>Here I mean generated in the Lie algebra sense. That is, the Hamiltonian produces infinitesimal (differential) translations in time, and the exponential of an generator gives the full translation. We'll see this soon.

**Single-particle QM** In single-particle quantum mechanics, we're interested in studying a particle moving in 1 dimension under some external potential  $V$ . Classically, we would use an action principle (we'll revisit this in the path integral formulation later). That is, we write down a Lagrangian

$$\mathcal{L} = \frac{1}{2}m\dot{x}^2 - V(x) \quad (4.9)$$

and we extremize the action  $\int dt \mathcal{L}(x, \dot{x})$ . However, for this part of the course we will instead use Hamiltonian language:

$$\mathcal{H} = p\dot{x} - \mathcal{L}, \quad p = \frac{\delta \mathcal{L}}{\delta \dot{x}}, \quad (4.10)$$

where the Hamiltonian is the Legendre transform of the Lagrangian, and thus if the potential depends only on  $x$  then

$$\mathcal{H} = \frac{1}{2m}p^2 + V(x), \quad (4.11)$$

in terms of the conjugate momentum  $p = m\dot{x}$ . Then we can write down Hamilton's equations, treating  $x$  and  $p$  as independent variables to find

$$\dot{x} = \frac{\partial \mathcal{H}}{\partial p}, \quad \dot{p} = -\frac{\partial \mathcal{H}}{\partial x}. \quad (4.12)$$

A particle's state is therefore represented by a point in phase space, i.e. the space of positions and momenta. For a particle in 1 dimension, the phase space is  $\mathbb{R}^2 = (x, p)$ , and in particular the phase space has an additional geometric structure. Namely, it is a *symplectic space*, meaning that a Poisson bracket is defined on this space.

**Definition 4.13.** Given two functions  $f(x, p), g(x, p)$ , the *Poisson bracket* of  $f, g$  is simply

$$\{f, g\} = \frac{\partial f}{\partial x} \frac{\partial g}{\partial p} - \frac{\partial f}{\partial p} \frac{\partial g}{\partial x}. \quad (4.14)$$

Hamilton's equations are nice in terms of Poisson brackets— they just become

$$\dot{x} = \{x, \mathcal{H}\}, \quad \dot{p} = \{p, \mathcal{H}\}. \quad (4.15)$$

Note that  $\frac{df}{dt} = \{f, \mathcal{H}\} + \frac{\partial f}{\partial t}$ , in the case where  $f$  may explicitly depend on time. Here,  $t$  is time parametrizing trajectories in phase space.

**Canonical quantization** Now for quantum mechanics. The procedure of going from a classical system to a quantum system is called *canonical quantization*. This is done by taking phase space variables  $x, p$  and uplfitting them to Hermitian operators  $\hat{x}, \hat{p}$ . We must also replace classical Poisson bracket relations between position and momentum with operator commutation relations (Lie brackets). Classically, the Poisson bracket between  $x, p$  is

$$\{x, p\} = 1. \quad (4.16)$$

In QM, this becomes

$$[\hat{x}, \hat{p}] = i\hbar, \quad (4.17)$$

with the commutator defined as

$$[\hat{A}, \hat{B}] \equiv \hat{A}\hat{B} - \hat{B}\hat{A}. \quad (4.18)$$

The commutator satisfies the following properties:

- i) linearity,  $[\hat{A}, \alpha_1 \hat{B} + \alpha_2 \hat{C}] = \alpha_1 [\hat{A}, \hat{B}] + \alpha_2 [\hat{A}, \hat{C}]$  and similar for the first argument;
- ii) The Jacobi identity,

$$[\hat{A}, [\hat{B}, \hat{C}]] + [\hat{B}, [\hat{C}, \hat{A}]] + [\hat{C}, [\hat{A}, \hat{B}]] = 0 \quad (4.19)$$

- iii) Leibniz rule,  $[\hat{A}, \hat{B}\hat{C}] = [\hat{A}, \hat{B}]\hat{C} + \hat{B}[\hat{A}, \hat{C}]$ .

The classical phase space is now replaced by a Hilbert space. All other observables become operators on Hilbert space, and this includes the Hamiltonian,

$$H(x, p) \rightarrow \hat{H}(\hat{x}, \hat{p}). \quad (4.20)$$

For a single particle in a simple potential, we can write it down immediately:

$$\hat{H}(\hat{x}, \hat{p}) = \frac{1}{2m} \hat{p}^2 + V(\hat{x}). \quad (4.21)$$

We should also note that classically,  $x$  and  $p$  commute. But quantum mechanically, they do not. Consider the classical function  $xp$  on phase space. What is its quantum equivalent? Well, it could be  $\hat{x}\hat{p}$ . Or it could be  $\hat{p}\hat{x}$ . Or it could be the symmetrized sum  $\frac{1}{2}(\hat{x}\hat{p} + \hat{p}\hat{x})$  (Weyl ordering). A priori, we do not know. This last option is popular, however.<sup>25</sup>

Finally, let us define a wavefunction.

**Definition 4.22.** A *wavefunction* is a state vector decomposed in the position eigenbasis. That is, let

$$\hat{x}|x\rangle = x|x\rangle \quad (4.23)$$

indicate the position eigenbasis. Then

$$\psi(x) = \langle x|\psi\rangle, \quad (4.24)$$

such that

$$|\psi\rangle = \int_{-\infty}^{\infty} dx |x\rangle \langle x|\psi\rangle = \int_{-\infty}^{\infty} dx |x\rangle \psi(x). \quad (4.25)$$

Lecture 5.

**Thursday, October 10, 2019**

**Quantum dynamics** In a quantum theory, time evolution is given by a unitary operator,

$$|\psi(t)\rangle = U(t, t_0)|\psi(t_0)\rangle. \quad (5.1)$$

Time evolution is determined by the Hamiltonian, a hermitian operator  $\hat{H} = \hat{H}^\dagger$ , such that

$$e^{i\hat{H}} \quad (5.2)$$

is unitary.<sup>26</sup>

For infinitesimal time evolution, notice that

$$U(t_0 + dt, t_0) = \mathbb{I} + \frac{dU}{dt} \Big|_{t=t_0} dt + O(dt^2). \quad (5.3)$$

If we choose  $U$  such that

$$\frac{dU}{dt} = -\frac{i\hat{H}}{\hbar}, \quad (5.4)$$

then we can recover

$$i\hbar \frac{\partial}{\partial t} |\psi(t)\rangle = \hat{H} |\psi(t)\rangle, \quad (5.5)$$

the *Schrödinger equation* in vector notation.

For the Hamiltonian

$$\hat{H} = \frac{\hat{p}^2}{2m} + V(\hat{x}), \quad (5.6)$$

we have

$$i\hbar \frac{\partial}{\partial t} |\psi(t)\rangle = \left[ \frac{\hat{p}^2}{2m} + V(\hat{x}) \right] |\psi(t)\rangle. \quad (5.7)$$

We can switch to the position basis, writing

$$\hat{p} = -i\hbar \frac{\partial}{\partial x}, \quad (5.8)$$

<sup>25</sup>For another example of Weyl ordering, we would associate

$$x^3 p \rightarrow \frac{1}{4}(\hat{x}^3 \hat{p} + \hat{x}^2 \hat{p} \hat{x} + \hat{x} \hat{p} \hat{x}^2 + \hat{p} \hat{x}^3).$$

<sup>26</sup>This is unitary because  $(e^{i\hat{H}})^\dagger = e^{-i\hat{H}^\dagger} = e^{-i\hat{H}} = (e^{i\hat{H}})^{-1}$ . More generally it comes from the fact that Hermitian operators form a Lie algebra which generates unitary transformations. We can build finite transformations by exponentiating the appropriate infinitesimal transformation.

from the canonical commutation relation  $[\hat{x}, \hat{p}] = i\hbar$ . If we then sandwich Eqn. 5.7 with a  $\langle x|$ , a position eigenstate, we get

$$i\hbar \frac{\partial}{\partial t} \psi(x, t) = -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} \psi(x, t) + V(x) \psi(x, t), \quad (5.9)$$

which is now the Schrödinger equation written in terms of the position space wavefunction.

The Schrödinger equation describes the evolution of  $|\psi(t)\rangle$ , but we can equivalently use it to understand  $U(t, t_0)$ . Notice that

$$\frac{\partial}{\partial t} U(t, t_0) = -\frac{i}{\hbar} \hat{H}(\hat{x}, \hat{p}, t) U(t, t_0) \quad (5.10)$$

with  $U(t_0, t_0) = \mathbb{I}$ . This follows from Eqn. 5.5 by substituting in  $|\psi(t)\rangle = U(t, t_0)|\psi(t_0)\rangle$  and noting the derivative is with respect to  $t$ , leaving  $|\psi(t_0)\rangle$  fixed. We can therefore write a formal solution for this equation. It looks almost like an exponential, except for the fact that the operators in the Hamiltonian may not commute at different times.<sup>27</sup>

Hence we get the formal solution for  $U$  (sometimes called Dyson's formula), written in terms of *time ordering*:

$$U(t, t_0) = \mathcal{T} \exp \left[ -\frac{i}{\hbar} \int_{t_0}^t dt' \hat{H}(\hat{x}, \hat{p}, t') \right]. \quad (5.11)$$

Here, the curly  $\mathcal{T}$  indicates time ordering, i.e. we must write the operators based on the time at which they are evaluated. We won't discuss this too much for now, since a proper discussion of this would basically be tantamount to explaining the path integral.

But the story becomes much simpler if the Hamiltonian is time-independent. In that case, our formal solution has no time ordering ambiguities, and we can immediately write down

$$U(t, t_0) = \exp \left[ -\frac{i}{\hbar} (t - t_0) \hat{H}(\hat{x}, \hat{p}) \right]. \quad (5.12)$$

Moreover this makes it clear that energy eigenstates (i.e. eigenstates of the Hamiltonian) evolve in time by phases,  $e^{-iEt/\hbar}$ .

**Schrödinger and Heisenberg pictures** Until now, we have been working in the Schrödinger picture, where operators are left fixed, so that *observables* carry no time dependence, and states are generically time-dependent. Thus expectation values are given by

$$\langle \psi(t) | \hat{A} | \psi(t) \rangle, \quad (5.13)$$

and all the time dependence is in our states' rotation in Hilbert space.

But there is an alternate way to do calculations, the *Heisenberg picture*. In the Heisenberg picture, state vectors carry no time dependence but operators do.<sup>28</sup> For a Schrödinger picture state  $|\psi(t)\rangle$ , it is certainly true that

$$\hat{A} |\psi(t)\rangle = \hat{A} U(t, t_0) |\psi(t_0)\rangle, \quad (5.14)$$

where  $t_0$  is some fixed earlier time. Since  $U$  is unitary we can also write this as

$$\hat{A} |\psi(t)\rangle = U(t, t_0) \left( U^\dagger(t, t_0) \hat{A} U(t, t_0) \right) |\psi(t_0)\rangle, \quad (5.15)$$

so that<sup>29</sup>

$$\langle \psi(t) | \hat{A} | \psi(t) \rangle = \langle \psi(t_0) | \left( U^\dagger(t, t_0) \hat{A} U(t, t_0) \right) | \psi(t_0) \rangle. \quad (5.16)$$

Call  $|\psi(t_0)\rangle$  the *Heisenberg state vector*, defined at some predetermined time  $t_0$ , and then the price we pay is that our operators have become time dependent,

$$\hat{A}(t) = U^\dagger(t, t_0) \hat{A}(t_0) U(t, t_0), \quad (5.17)$$

where  $\hat{A}(t)$  indicates the Heisenberg picture version of  $\hat{A}$ .

<sup>27</sup>This leads to equal-time commutation relations in the appropriate picture of QM.

<sup>28</sup>If you like, we regroup all the time dependence into the operators.

<sup>29</sup>Mukund mentioned some mnemonic for why daggers go on the left of operators. I don't know what his is, but this is how I remember it. Write the time-dependent expectation value in Schrödinger picture and regroup the  $U$ s into the operator.

Note that for a time-independent Hamiltonian,

$$\hat{A}(t) = e^{\frac{i}{\hbar}(t-t_0)\hat{H}} \hat{A}(t_0) e^{-\frac{i}{\hbar}(t-t_0)\hat{H}}, \quad (5.18)$$

and the only way to evaluate this is to Taylor expand as

$$\hat{A}(t) = \left( \mathbb{I} + \frac{i}{\hbar}(t-t_0)\hat{H} + \left(\frac{i}{\hbar}\right)^2 (t-t_0)^2 \frac{\hat{H}^2}{2!} + \dots \right) \hat{A}(t_0) \left( \mathbb{I} - \frac{i}{\hbar}(t-t_0)\hat{H} + \left(-\frac{i}{\hbar}\right)^2 (t-t_0)^2 \frac{\hat{H}^2}{2!} + \dots \right) \quad (5.19)$$

and we claim (exercise) that every other term is of the form of a nested commutator,

$$\hat{A}(t_0) + \frac{i}{\hbar}(t-t_0)[\hat{H}, \hat{A}(t_0)] + (\#)[\hat{H}, [\hat{H}, \hat{A}(t_0)]] + \dots \quad (5.20)$$

where  $\#$  is some numerical factor we have not worked out yet. This fact will be important on the homework.

Incidentally, this tells us that where states evolve by rotations, operators generically transform in some complicated way. This has become a point of interest in the study of quantum chaos, how the time evolution of operators in the Heisenberg picture may depend very sensitively on the initial conditions.

**Generalizations** Here, we have considered the case of a single particle moving in 1D, but more generally we could have a particle moving in  $d$  space direction so that the position and momentum operators have  $d$  components,

$$\hat{x}_i, i = 1, \dots, d, \quad \hat{p}_j, j = 1, \dots, d, \quad (5.21)$$

obeying the commutation relations

$$[\hat{x}_i, \hat{p}_j] = i\hbar\delta_{ij}, \quad (5.22)$$

and in the Schrodinger equation, the  $\hat{p}^2$  becomes the Laplacian in  $d$  spatial coordinates,

$$\nabla^2 = \sum_{i=1}^d \frac{\partial^2}{\partial x_i^2}. \quad (5.23)$$

However, the generalization to multiple particles is more subtle. If our one-particle states live in Hilbert spaces  $\mathcal{H}_1, \mathcal{H}_2, \dots$  then the total Hilbert space is not just the direct sum  $\oplus$  but the tensor product

$$\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2. \quad (5.24)$$

Hence if  $\{|\psi_i\rangle\}_{i=1}^n$  generate  $\mathcal{H}_1$  and  $\{|\chi_j\rangle\}_{j=1}^m$  generate  $\mathcal{H}_2$ , then  $\mathcal{H}$  is generated by *tensor products*

$$|\psi_i\rangle \otimes |\chi_j\rangle, \quad (5.25)$$

and  $\mathcal{H}$  is  $m \times n$ -dimensional. It is this tensor product structure that is at the heart of the characteristic weirdness of quantum mechanics, namely the phenomenon known as *entanglement*.

**The harmonic oscillator (Shankar Ch. 7)** The quantum harmonic oscillator is a wonderful thing.<sup>30</sup> To begin, the classical harmonic oscillator is basically just a particle sitting in a parabolic (quadratic) potential. Its Lagrangian is

$$L = \frac{1}{2}m\dot{x}^2 - \frac{1}{2}m\omega^2 x^2, \quad (5.26)$$

with corresponding Hamiltonian

$$H = \frac{p^2}{2m} + \frac{1}{2}m\omega^2 x^2. \quad (5.27)$$

Canonical quantization tells us to promote  $x$  and  $p$  to operators obeying the canonical commutation relation

$$[\hat{x}, \hat{p}] = i\hbar, \quad (5.28)$$

so that

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2 \hat{x}^2 \hat{H} \quad (5.29)$$

$$= -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \frac{1}{2}m\omega^2 \hat{x}^2, \quad (5.30)$$

<sup>30</sup>Not official lecture content. Just my (correct) opinion.

where we have rewritten  $\hat{p}$  in the position basis.

Let us try to find the eigenspectrum of the Hamiltonian, i.e. the state vectors such that

$$\hat{H}|\psi(t)\rangle = E|\psi(t)\rangle. \quad (5.31)$$

The Schrödinger equation tells us that energy eigenstates evolve in a special way, namely by

$$|\psi(t)\rangle = e^{-iEt/\hbar}|\psi(0)\rangle. \quad (5.32)$$

Hence the Schrodinger equation written in terms of the position basis wavefunctions becomes

$$\left(-\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \frac{1}{2}m\omega^2 x^2\right)\psi(x) = E\psi(x). \quad (5.33)$$

This is a second-order ODE for  $\psi$ :

$$\frac{d^2\psi}{dx^2} + \left(\frac{2mE}{\hbar^2} - \frac{1}{2} \frac{m^2\omega^2}{\hbar^2} x^2\right)\psi = 0. \quad (5.34)$$

We can simplify by defining

$$\frac{E}{\hbar\omega} = \epsilon, \quad (5.35)$$

$$x = \sqrt{\frac{\hbar}{m\omega}} \xi. \quad (5.36)$$

In these variables, our equation becomes<sup>31</sup>

$$\frac{d^2\psi}{d\xi^2} + (2\epsilon - \xi^2)\psi = 0. \quad (5.37)$$

For such equations, we expect two families of solutions fitting the boundary conditions, one of which will be excluded on physical grounds. Typically we will have a condition on  $\epsilon$ , telling us that the energy is quantized.

Suppose we didn't have a computer to find the solutions to this equation right away. How do we study this equation? One way is to look at its limiting behavior. As  $\xi \rightarrow \infty$ , our equation reduces to

$$\frac{d^2\psi}{d\xi^2} - \xi^2\psi = 0, \quad (5.38)$$

with solutions

$$\psi = c_1 \xi^m e^{\xi^2/2} + c_2 \xi^m e^{-\xi^2/2}. \quad (5.39)$$

But this first term grows exponentially as  $\xi \rightarrow \infty$  (equivalent to  $x \rightarrow \infty$ , so we should exclude that on physical grounds (normalization, if you like).

In the limit  $\xi \rightarrow 0$ , we have instead

$$\frac{d^2\psi}{d\xi^2} + 2\epsilon\psi = 0, \quad (5.40)$$

with solutions

$$\psi = a_1 \cos(\sqrt{2\epsilon}\xi) + a_2 \sin(\sqrt{2\epsilon}\xi), \quad (5.41)$$

so we haven't learned much from expanding about the origin.

<sup>31</sup>This is a good strategy for physical problems in general. Defining dimensionless variables often gives us a sense of the important scales in the problem, e.g. energy is naturally measured in units of  $\hbar\omega$ . Sometimes we also recognize a differential equation as e.g. Hermite's equation or Legendre's equation when we write it in dimensionless form; a bit of familiarity with some common second-order equations can save a lot of time.

**Tuesday, October 15, 2019**

Last time, we defined the dimensionless variables  $\xi, \epsilon$  in terms of  $x$  and  $E$  in order to write the Schrödinger equation in a dimension-free way:

$$\frac{d^2\psi(\xi)}{d\xi^2} + (2\epsilon - \xi^2)\psi(\xi) = 0. \quad (6.1)$$

We suggested that there was some limiting behavior where as  $\xi \rightarrow \infty$ ,

$$\psi(\xi) = c_1 \xi^k e^{-\xi^2/2} + c_2 \xi^k e^{\xi^2/2}, \quad (6.2)$$

setting  $c_2 = 0$  for convergence. We also had some expansion in sines and cosines about the origin as  $\xi \rightarrow 0$ .

Let us redefine

$$\psi(\xi) = \phi(\xi) e^{-\frac{1}{2}\xi^2} \quad (6.3)$$

so that substituting (exercise), the Schrödinger equation becomes

$$\frac{d^2\phi}{d\xi^2} - 2\xi \frac{d\phi}{d\xi} + (2\epsilon - 1)\phi(\xi) = 0. \quad (6.4)$$

We shall solve this by the Frobenius method, i.e. by expanding  $\phi$  as a power series in  $\xi$ . Let

$$\phi(\xi) = \sum_{n=0}^{\infty} a_n \xi^n, \quad (6.5)$$

so that our equation becomes

$$\sum_{n=0}^{\infty} a_n n(n-1) \xi^{n-2} - 2\xi \sum_{n=0}^{\infty} a_n n \xi^{n-1} + (2\epsilon - 1) \sum_{n=0}^{\infty} a_n \xi^n = 0. \quad (6.6)$$

Note that the first sum really starts from  $n = 2$  since the  $n = 0, n = 1$  terms are zero, and the second term is similar. Hence we can combine all these sums:

$$\sum_{j=0}^{\infty} [(j+1)(j+2)a_{j+2} - (2j+1-2\epsilon)a_j] \xi^j = 0. \quad (6.7)$$

That is, we collect terms in powers of  $\xi$ , redefining some indices. Note that on the space of smooth functions defined on  $\mathbb{R}$ , the functions  $\{\xi^j\}_{j=0}^{\infty}$  form a complete, linearly independent basis. That means this equation gives us a recursion relation for the coefficients  $a_j$  of  $\phi$ , because the only way for the sum of all  $\xi^j$  to be zero is if each of the individual coefficients vanish. Hence

$$a_{j+2} = \frac{2j+1-2\epsilon}{(j+1)(j+2)} a_j. \quad (6.8)$$

For a generic second-order equation, we can always find such a recursion relation which will generally involve  $a_j, a_{j+1}, a_{j+2}$ .

The relation (6.8) relates even  $j$  coefficients to each other, and it relates odd  $j$  coefficients to each other, but it does not mix them. This agrees with our intuition that there should be two linearly independent sets of solutions (the power law exponentials in the large  $\xi$  limit and the sines and cosines in the small  $\xi$  limit).

Hence the solutions separate into those determined by  $a_0$  and those determined by  $a_1$ :

$$\phi(\xi) = a_0 \left[ 1 + \frac{1-2\epsilon}{2!} \xi^2 + \frac{(1-2\epsilon)(5-2\epsilon)}{4!} \xi^4 + \dots \right] + a_1 \left[ \xi + \frac{(3-2\epsilon)}{3!} \xi^3 + \frac{(3-2\epsilon)(7-2\epsilon)}{5!} \xi^5 + \dots \right]. \quad (6.9)$$

Notice that as  $\xi \rightarrow 0$ ,  $\phi(\xi)$  is determined by  $a_0, a_1$ , which are otherwise unconstrained. To find what happens as  $\xi \rightarrow \infty$ , we have

$$\frac{a_{j+2}}{a_j} = \frac{2j+1-2\epsilon}{(j+1)(j+2)} \approx \frac{2j}{j^2} \approx \frac{2}{j}, \quad j \gg 1. \quad (6.10)$$

That is, in the large  $\xi$  limit (equivalently in the limit of  $j$  large), for  $j \geq j_c \gg 1$ , our solution is approximately

$$a_{j_c} \xi^{j_c} \left( 1 + \frac{2}{j_c} \xi^2 + \frac{4}{j_c(j_c+2)} \xi^4 + \dots \right). \quad (6.11)$$

That is, pick some  $j_c$  large, look at all terms of power  $\xi^{j_c}$  or higher, and WLOG consider just the even or odd terms. Then this solution can be explicitly summed; it is

$$a_{j_c} \xi^{j_c} e^{\xi^2}, \quad (6.12)$$

and this tells us that we actually got back this bad exponential behavior in  $\xi$ . This is exactly like the  $c_2 \xi^k e^{\xi^2/2}$  term we tried to get rid of. We could have expected this— for a generic solution, we have not yet imposed the physical boundary conditions for convergence.

So how do we do this? Independent of  $a_0, a_1$ , we have a divergent solution as  $\xi \rightarrow \infty$ . It must be that our infinite sum actually terminates at some finite  $j$ . We have three choices to impose the boundary conditions.

- i) We can set  $a_0 = a_1 = 0$ , the trivial solution.
- ii) Let  $a_0$  be arbitrary and set  $a_1 = 0$ .
- iii) Let  $a_1$  be arbitrary and set  $a_0 = 0$ .

In either case ii or iii, we must set

$$\epsilon = \frac{2n+1}{2} \quad (6.13)$$

so that the series terminates at order  $n$ , i.e.

$$a_{n+2} = \frac{2n+1-2(2n+1)/2}{(n+1)(n+2)} a_j = 0. \quad (6.14)$$

Since  $\epsilon$  is related to the (dimensionful) energy  $E$ , this constraint tells us the spectrum of the harmonic oscillator.

Let us redefine

$$\psi(\xi) = \phi(\xi) e^{-\frac{1}{2}\xi^2}, \quad (6.15)$$

where the solutions are  $\phi_n(\xi)$  with  $\epsilon = n + 1/2$ . The particular solutions are *Hermite polynomials*  $H_n(\xi)$ , where the first we are

$$\begin{aligned} H_0(\xi) &= 1 \\ H_1(\xi) &= \xi \\ H_2(\xi) &= 2(2\xi^2 - 1), \end{aligned}$$

where these Hermite polynomials have a generating function

$$e^{-\alpha^2 + 2\alpha\xi} = \sum_{n=0}^{\infty} \frac{H_n(\xi)}{n!} \alpha^n, \quad (6.16)$$

up to normalization. The Hermite polynomials also form a complete basis for smooth functions like the monomials  $\xi^j$ .

Restoring units we get some explicit solutions for the harmonic oscillator eigenstates, i.e. the wavefunctions

$$\psi_n(x) = \left( \frac{m\omega}{2^{2n}(n!)^2\pi\hbar} \right)^{1/4} e^{-\frac{m\omega}{2\hbar}x^2} H_n\left(\sqrt{\frac{m\omega}{\hbar}}x\right) \quad (6.17)$$

satisfy the Schrödinger equation for the harmonic oscillator potential,

$$\hat{H}\psi_n(x) = E_n\psi_n(x), \quad (6.18)$$

with an energy spectrum given by

$$E_n = (n + 1/2)\hbar\omega. \quad (6.19)$$

Looking at the  $n = 0$  ground state, we see it is just a (normalized) Gaussian. However, it differs in one important way from the classical solution. For a solution with energy  $E_0 = \hbar\omega/2$ , a classical particle would never escape the potential well, i.e. it must stay within  $|x| \leq \sqrt{\hbar/m\omega}$ . But the quantum solution (and more importantly its modulus squared,  $|\psi_n(x)|^2$ ) is nonzero in the classically forbidden region. So there is an (exponentially damped) probability of observing the particle outside the classically forbidden region. Note

also that the ground state is node-free,  $\psi_0 > 0$  everywhere. More generally, the  $n$ th excited state has  $n$  zeros corresponding to  $H_n(\xi) = 0$ .

Here's another takeaway from this problem. The discreteness of energy levels defines the "quantization" of the system, and this is generally true for a confining potential. There are no nodes in the ground state, and the energy levels have some quantization condition. Moreover, there exists an isomorphism of Hilbert spaces between such confining potentials, i.e. the wavefunctions are  $\psi_m(x)$ ,  $m = 0, 1, 2, \dots$  and form some countably infinite set.

Note that confining potentials differ from potentials that vanish at infinity. Potentials of the latter kind will have not just bound states but also scattering states which are not normalizable and will generally form a continuous spectrum.

**The algebraic method** The Frobenius method requires us to know how to solve differential equations. The series method is very general, but there is another method that will prove useful.<sup>32</sup> Let us define creation and annihilation operators

$$a = \frac{1}{\sqrt{2}} \left( \sqrt{\frac{m\omega}{\hbar}} \hat{x} + \frac{i}{\sqrt{\hbar m \omega}} \hat{p} \right), \quad (6.20)$$

$$a = \frac{1}{\sqrt{2}} \left( \sqrt{\frac{m\omega}{\hbar}} \hat{x} - \frac{i}{\sqrt{\hbar m \omega}} \hat{p} \right). \quad (6.21)$$

Note that  $x = x^\dagger$ ,  $p = p^\dagger$ , so

$$[x, p] = i\hbar \implies [a, a^\dagger] = 1. \quad (6.22)$$

Hence we can "factor" the Hamiltonian. Writing

$$\hat{H} = \hbar\omega \left( \frac{p^2}{2m\hbar\omega} + \frac{m\omega}{2\hbar} x^2 \right), \quad (6.23)$$

we see that in terms of  $a, a^\dagger$  our Hamiltonian becomes

$$\begin{aligned} H &= \frac{\hbar\omega}{2} (a^\dagger a + a a^\dagger) \\ &= \hbar\omega (a^\dagger a + 1/2), \end{aligned} \quad (6.24)$$

where we have used the commutation relation  $aa^\dagger - a^\dagger a = 1$  in the second line.

Let us now define the *number operator*

$$N \equiv a^\dagger a. \quad (6.25)$$

It commutes with the Hamiltonian,  $[H, N] = 0$ , so we may as well find the eigenstates of  $N$  since they will be eigenstates of  $H$ , with some shifted eigenvalues. Moreover

$$\begin{aligned} [N, a] &= [a^\dagger a, a] = a^\dagger a a - a a^\dagger a \\ &= (a^\dagger a - a a^\dagger) a = -a. \end{aligned} \quad (6.26)$$

Similarly

$$[N, a^\dagger] = a^\dagger. \quad (6.27)$$

We can use these two relations to compute the commutator of  $a$  and  $a^\dagger$  with the Hamiltonian:

$$[H, a] = -\hbar\omega a, \quad [H, a^\dagger] = \hbar\omega a^\dagger. \quad (6.28)$$

That is, acting on some eigenstate  $|n\rangle$  of energy  $E_n$ ,  $a^\dagger|n\rangle$  produces a new eigenstate of energy  $E_n + \hbar\omega$  and similarly  $a|n\rangle$  produces an eigenstate of energy  $E_n - \hbar\omega$ .

For suppose that  $N$  has an eigenvector  $|\nu\rangle$  with eigenvalue  $\nu$ . That is,

$$N|\nu\rangle = \nu|\nu\rangle. \quad (6.29)$$

Then  $a|\nu\rangle$  is also an eigenvector of  $N$  with eigenvalue  $\nu - 1$ :

$$N(a|\nu\rangle) = Na|\nu\rangle = (aN - a)|\nu\rangle = a(N - 1)|\nu\rangle = (\nu - 1)(a|\nu\rangle). \quad (6.30)$$

<sup>32</sup>Especially if you ever do quantum field theory.

Moreover

$$(a|\nu\rangle)^\dagger = \langle\nu|a^\dagger, \quad (6.31)$$

so

$$||a|\nu\rangle||^2 = \langle\nu|a^\dagger a|\nu\rangle = \langle\nu|N|\nu\rangle = \nu\langle\nu|\nu\rangle. \quad (6.32)$$

But the norm of this new state depends on  $\nu$ , so we must be careful. By repeatedly applying  $a$  we get a state  $a^k|\nu\rangle$  such that

$$N(a^k|\nu\rangle) = (\nu - k)a^k|\nu\rangle. \quad (6.33)$$

But since the norm depends on  $\nu$ , which can be lowered, there must be some state  $a^k|\nu\rangle$  where the norm becomes negative. We must stop, or else  $\nu - k$  could become (arbitrarily) negative. All states in our Hilbert space must have non-negative norm.

Hence there exists some state that is annihilated by  $a$ , i.e.

$$a|0\rangle = 0, \quad (6.34)$$

and it follows that

$$N|0\rangle = 0. \quad (6.35)$$

Is there a ceiling? By the same manipulations, we find that

$$Na^\dagger|\nu\rangle = (\nu + 1)a^\dagger|\nu\rangle, \quad (6.36)$$

so we can construct arbitrarily high number eigenstates with the raising operator. So there is no ceiling in the eigenspectrum.<sup>33</sup> We may write

$$Na^\dagger|0\rangle = 1a^\dagger|0\rangle, \quad (6.37)$$

so we see that  $a^\dagger|0\rangle$  is an eigenstate of  $N$  with eigenvalue 1. Define

$$|1\rangle = a^\dagger|0\rangle \quad (6.38)$$

and more generally

$$|k\rangle = \frac{1}{\sqrt{k!}}(a^\dagger)^k|0\rangle, \quad (6.39)$$

where the factorial accounts for normalization.

In general,

$$N|k\rangle = k|k\rangle, \quad a|k\rangle = \sqrt{k}|k-1\rangle, \quad a^\dagger|k\rangle = \sqrt{k+1}|k+1\rangle. \quad (6.40)$$

We now see that  $N$  has an eigenspectrum in integer steps starting from  $|0\rangle$  and going up to arbitrarily high  $|k\rangle$ .

But now we're done,<sup>34</sup> because  $H$  has the same eigenstates as  $N$ .

$$H|k\rangle = \hbar\omega(k + 1/2)|k\rangle. \quad (6.41)$$

To construct the wavefunctions in position basis, just use

$$a = \frac{1}{\sqrt{2}}(\xi + \frac{d}{d\xi}), \quad a^\dagger = \frac{1}{\sqrt{2}}(\xi - \frac{d}{d\xi}), \quad (6.42)$$

where  $\xi = \sqrt{m\omega/\hbar}x$ , and then

$$a|0\rangle \implies (\xi + \frac{d}{d\xi})\psi(\xi) = 0 \implies \psi_0(\xi) = a_0 e^{-\xi^2/2}. \quad (6.43)$$

This is a much easier differential equation to solve than the second-order one from earlier.<sup>35</sup> And now we can construct the other states using

$$|k\rangle = \frac{1}{k!}(a^\dagger)^k|0\rangle, \quad (6.44)$$

<sup>33</sup>But contrast the angular momentum operator  $L_z$  (and its operators  $L^+, L^-$ ) later.  $L_z$  has both minimum and maximum eigenvalues, so the ladder is finite.

<sup>34</sup>We haven't yet shown that the ground state is unique, but we can show that because this space of solutions is isomorphic to the solutions we constructed analytically, the ground state is in fact unique. We could also prove this by contradiction. But see the next footnote for a nice way to do it.

<sup>35</sup>Actually, since this equation is first-order, we can fix  $a_0$  by normalization (up to a complex phase), which completely determines the ground state. This proves uniqueness of the ground state.

which gives (explicitly)

$$\psi_k(\xi) = \frac{1}{\sqrt{k!}} \frac{1}{2^{k/2}} \left( \xi - \frac{d}{d\xi} \right)^k e^{-\xi^2/2}, \quad (6.45)$$

and the Hermite polynomials are

$$H_n(\xi) = e^{\xi^2/2} \left( \xi - \frac{d}{d\xi} \right)^n e^{-\xi^2/2}. \quad (6.46)$$

Lecture 7.

**Thursday, October 17, 2019**

Today we'll wrap up our discussion of the harmonic oscillator and then move on to more general topics.

**Coherent states** Last time, we talked about the creation and annihilation operators. Recall that

$$a = \alpha_1 \hat{x} + \alpha_2 i \hat{p}, \quad a^\dagger = \alpha_1 \hat{x} - \alpha_2 i \hat{p} \quad (7.1)$$

for real constants  $\alpha_1, \alpha_2$ . While  $a$  and  $a^\dagger$  are not hermitian, perhaps eigenstates exist. Let us consider the state

$$|\zeta\rangle = e^{\zeta a^\dagger} |0\rangle \quad (7.2)$$

$$= \left[ \sum_{n=0}^{\infty} \frac{\zeta^n}{n!} (a^\dagger)^n \right] |0\rangle \quad (7.3)$$

$$= \sum_{n=0}^{\infty} \frac{\zeta^n}{\sqrt{n!}} |n\rangle. \quad (7.4)$$

We now claim that  $|\zeta\rangle$  is an eigenstate of  $a$ . We can show this explicitly:

$$a|\zeta\rangle = \sum_{n=0}^{\infty} \frac{\zeta^n}{\sqrt{n!}} |n\rangle = \sum_{n=1}^{\infty} \frac{\zeta^n}{\sqrt{(n-1)!}} |n-1\rangle = \zeta \sum_{n=1}^{\infty} \frac{\zeta^{n-1}}{\sqrt{(n-1)!}} |(n-1)\rangle = \zeta |\zeta\rangle. \quad (7.5)$$

Hence  $|\zeta\rangle$  is an eigenstate of  $a$  with complex eigenvalue  $\zeta$ , and this is fine since  $a$  is not hermitian. Similarly  $\langle 0|e^{\zeta^* a}$  has the interpretation of being an eigenstate of  $a^\dagger$  in the sense that

$$\left( \langle 0|e^{\zeta^* a} \right) a^\dagger = \zeta^* \left( \langle 0|e^{\zeta^* a} \right). \quad (7.6)$$

Moreover, the coherent states form a complete basis for the Hilbert space, albeit a very different-looking one than the energy eigenstates. Curiously, it looks as though we have gotten too many states (i.e. these are parametrized by an uncountable infinity of complex parameters  $\zeta$ , whereas the number states are a countable basis). But we will show that we can write a resolution of the identity in terms of the coherent states, which tells us that we indeed have a basis.

Notice that  $a$  has ket eigenvectors, whereas  $a^\dagger$  has bra eigenvectors. The converse is not true. The operator  $a$  only has *right eigenvectors* but no *left eigenvectors*, i.e.  $\nexists \langle \mu|a = f(\mu)\langle \mu|$ , and an equivalent statement holds for  $a^\dagger$ .<sup>36</sup> This is different from the position operator (which is hermitian), such that

$$\hat{x}|x\rangle = x|x\rangle \implies \langle x|\hat{x} = x\langle x|. \quad (7.7)$$

Note this is generally true for any hermitian operator, since  $A|v\rangle = \lambda|v\rangle \implies \langle v|A = \langle v|A^\dagger = \lambda^* \langle v| = \lambda \langle v|$ .

Let us also remark that

$$\langle \zeta_1|\zeta_2\rangle = \langle 0|e^{\zeta_1^* a} e^{\zeta_2 a^\dagger} |0\rangle. \quad (7.8)$$

How do we evaluate this? We cannot simply add the exponentials since  $a, a^\dagger$  do not commute. However, if

$$[A, [A, B]] = [B, [A, B]] = 0 \quad (7.9)$$

<sup>36</sup>Why is this true? Consider writing a general state as a linear combination of the  $|n\rangle$  states, and then notice that  $a^\dagger$  cannot create the vacuum state. Hence the coefficient of the vacuum state must be zero. And the next coefficient up must therefore be zero. And so on. With  $a$ , all the states come down; with  $a^\dagger$  we always miss the vacuum  $|0\rangle$ .

then

$$e^A e^B = e^B e^A e^{[A,B]}. \quad (7.10)$$

We haven't proved this formula but maybe later. More generally,

$$e^A e^B = e^C \quad (7.11)$$

where

$$C = A + B + \frac{1}{2}[A, B] + \frac{1}{12}[A, [A, B]] - \frac{1}{12}[B, [A, B]] + \dots \quad (7.12)$$

where the  $\dots$  indicates higher commutators.<sup>37</sup> This is the Baker-Campbell-Hausdorff (BCH) formula.

Let us observe that since  $[a, a^\dagger] = 1$ , we have  $[a, [a, a^\dagger]] = [a^\dagger, [a, a^\dagger]] = 0$ , so

$$e^{\zeta_1^* a} e^{\zeta_2 a^\dagger} = e^{\zeta_2 a^\dagger} e^{\zeta_1^* a} e^{[\zeta_2 a^\dagger, \zeta_1^* a]}, \quad (7.13)$$

where this commutator term is  $e^{\zeta_1^* \zeta_2}$ , just a c-number. Hence

$$\langle 0 | e^{\zeta_1^* a} e^{\zeta_2 a^\dagger} | 0 \rangle = \langle 0 | e^{\zeta_2 a^\dagger} e^{\zeta_1^* a} | 0 \rangle e^{\zeta_1^* \zeta_2} \quad (7.14)$$

$$= e^{\zeta_1^* \zeta_2} \langle 0 | \left( 1 + \zeta_2 a^\dagger + \frac{1}{2!} \zeta_2^2 (a^\dagger)^2 + \dots \right) \left( 1 + \zeta_1^* a + \frac{1}{2!} (\zeta_1^*)^2 a^2 + \dots \right) | 0 \rangle \quad (7.15)$$

$$= e^{\zeta_1^* \zeta_2} \langle 0 | 0 \rangle = e^{\zeta_1^* \zeta_2}. \quad (7.16)$$

Rule of thumb working with harmonic oscillators: put all annihilation operators on the right and all the creation operators on the left.<sup>38</sup>

As we've said, the  $\{|\zeta\rangle\}$  states for  $\zeta \in \mathbb{C}$  are an overcomplete set, but the following identity is true:

$$\mathbb{I} = \frac{1}{2\pi i} \int d^2 \zeta |\zeta\rangle \langle \zeta| e^{-|\zeta|^2}, \quad (7.17)$$

with  $d^2 \zeta = d\zeta d\zeta^*$ .<sup>39</sup> In writing this, we've used the normalization that we just computed,  $\langle \zeta | \zeta \rangle = e^{|\zeta|^2}$ .

**Free particle** Now that we have discussed the harmonic oscillator, let us go to a seemingly simpler problem, that of the free particle. The harmonic oscillator is an example of a (regular) confining potential, one where  $V(x) \rightarrow \infty$  as  $|x| \rightarrow \infty$ . Confining potentials have a discrete spectrum of bound states (those with wavefunction decaying as  $|x| \rightarrow \infty$ ).

However, there is another relevant class of states. When particles can escape to infinity, we have *scattering states*. We can understand these by studying the free particle. The free particle has  $V = 0$  everywhere, so that the Hamiltonian is

$$\hat{H} = \frac{\hat{p}^2}{2m}. \quad (7.18)$$

It's traditional to solve this in the Schrödinger picture, but we're not going to do this just yet. For notice that the Hamiltonian commutes with  $\hat{p}$ , i.e.

$$[\hat{H}, \hat{p}] = 0. \quad (7.19)$$

Hence momentum eigenstates are also energy eigenstates of  $H$ . That is, in the momentum basis,

$$\hat{p}|k\rangle = k|k\rangle, \quad (7.20)$$

where we will require  $k \in \mathbb{R}$  in order for certain boundary conditions to be satisfied. Then

$$\hat{H}|k\rangle = \frac{k^2}{2m}|k\rangle, \quad (7.21)$$

which tells us that  $E(k) = \frac{k^2}{2m}$ . This reminds us of an important lesson—when you have a problem in quantum mechanics, you should think about what basis is best to solve the problem in. This often saves us a lot of time rather than trying to brute-force our way through the Schrödinger equation.

Conversely if we want an energy eigenstate of some energy  $E$ ,  $\hat{H}|E\rangle = E|E\rangle$ , then

$$k = \pm \sqrt{2mE}. \quad (7.22)$$

<sup>37</sup>We can also write it more nicely in terms of an adjoint action.

<sup>38</sup>That is, write them in normal ordering. We do this a lot in QFT.

<sup>39</sup>We could probably check this by expressing a general state as a sum of the energy eigenstates.

This quadratic relation is forced upon us by the fact we are studying non-relativistic quantum mechanics, where  $E = p^2/2m$ . Hence a general energy eigenstate can be written as

$$|E\rangle = \alpha_+ |k = \sqrt{2mE}\rangle + \alpha_- |k = -\sqrt{2mE}\rangle, \quad (7.23)$$

a linear combination of two momentum eigenstates which correspond to left-moving particles and right-moving particles. Let us now take our eigenvalue expression and sandwich it with  $\langle x|$ :

$$\langle x|\hat{p}|k\rangle = k\langle x|k\rangle. \quad (7.24)$$

Equivalently, notice that we can write  $\hat{p}$  in the position basis,

$$\langle x|\left(-i\hbar\frac{d}{dx}\right)|k\rangle, \quad (7.25)$$

and as  $p$  is self-adjoint we can make it act on the  $\langle x|$ , namely by rewriting as

$$-i\hbar\frac{d}{dx}\langle x|k\rangle = k\langle x|k\rangle. \quad (7.26)$$

Now  $\langle x|k\rangle$  is some function of  $k$  and  $x$ , with solution

$$\langle x|k\rangle = Ce^{ikx/\hbar}, \quad (7.27)$$

which is simply our plane wave solution. Hence

$$|k\rangle = \int_{-\infty}^{\infty} dx |x\rangle \langle x|k\rangle, \quad (7.28)$$

with  $\langle x|k\rangle$  as above. We now see that

$$\psi_E(x) = \langle x|E\rangle \quad (7.29)$$

$$= \frac{\alpha_+}{(2\pi\hbar)^{1/2}} e^{\frac{i}{\hbar}\sqrt{2mE}x} + \frac{\alpha_-}{(2\pi\hbar)^{1/2}} e^{-\frac{i}{\hbar}\sqrt{2mE}x}. \quad (7.30)$$

Note that the factor of  $1/\sqrt{2\pi\hbar}$  is part of taking the Fourier transform to get back to position space; we can either have factors like this in both the Fourier transform and the inverse transform, or we can keep them all in e.g. the inverse transform. We'll stick with the symmetric normalization for now.

In general, we can now write down a Gaussian wavepacket

$$\psi(x, t=0) = e^{ikx} e^{-\frac{1}{2\delta_x^2}x^2}. \quad (7.31)$$

Notice that  $\langle x \rangle = 0$  since this particle is localized to the origin, but it has a nonzero variance,

$$\Delta x = \sqrt{\langle (x - \langle x \rangle)^2 \rangle} = \frac{1}{\sqrt{2}}\delta_x. \quad (7.32)$$

Similarly one may compute

$$\langle p \rangle = k\hbar, \quad \Delta p = \frac{\hbar}{\sqrt{2}\delta_x}. \quad (7.33)$$

Hence this looks like a particle initialized at  $t = 0$  with some momentum  $k\hbar$ . One may also check readily that

$$\Delta x \Delta p = \frac{\hbar}{2}, \quad (7.34)$$

so Heisenberg uncertainty is saturated.

How does this wavepacket evolve in time? By a unitary operator, as usual.

$$\psi(x, t) = U(t, 0)\psi(x, t=0) \quad (7.35)$$

$$= e^{-iHt/\hbar}\psi(x, t=0) \quad (7.36)$$

$$= e^{-\frac{ip^2t}{2m\hbar}}\psi(x, t=0) \quad (7.37)$$

$$= e^{\frac{it}{\hbar}\left(\frac{\hbar^2}{2m}\frac{d^2}{dx^2}\right)}\psi(x, 0). \quad (7.38)$$

And we can now study the effect on our Gaussian wavepacket. The solution is

$$\psi(x, t) = \frac{1}{\sqrt{\sqrt{\pi}\delta_x\left(1 + \frac{i\hbar t}{m\delta_x^2}\right)}} \exp\left[ik\left(x - \frac{k\hbar t}{m}\right) - \frac{1}{2\delta_x^2\left(1 + \frac{i\hbar t}{m\delta_x^2}\right)}\left(x - \frac{k\hbar t}{m}\right)^2\right]. \quad (7.39)$$

It looks horrible, but it has a nice physical interpretation. What we're seeing is that the peak has moved– it picks up an offset of  $\frac{k\hbar t}{m}$ , so that

$$\langle x(t) \rangle = \frac{k\hbar t}{m}. \quad (7.40)$$

It also spreads out to have a new width of

$$\Delta x(t) = \frac{1}{\sqrt{2}}\delta_x\sqrt{1 + \frac{\hbar^2 t^2}{m^2\delta_x^4}}, \quad (7.41)$$

and in the limit as  $t$  grows large, this expression becomes

$$\frac{1}{\sqrt{2}}\frac{\hbar t}{m\delta_x}. \quad (7.42)$$

It follows that

$$\langle x \rangle = \frac{\hbar k t}{m} = \frac{\langle p \rangle}{m} t, \quad (7.43)$$

so we see that the expectation values (not operators!) follow classical relations.

As time goes on, we see that the localization of the particle in position fades away, while the total probability to find the particle anywhere remains 1 (as it must under unitary time evolution).

Lecture 8.

**Tuesday, October 22, 2019**

Last time we discussed the free particle wavefunctions, which are scattering states in  $\mathbb{R}^n$ . That is, for  $\mathcal{H} = \frac{\hat{\mathbf{p}} \cdot \hat{\mathbf{p}}}{2m}$ , our solutions are

$$\psi_{\mathbf{k}}(\mathbf{x}) = \frac{1}{(2\pi\hbar)^{d/2}} \exp(i\mathbf{k} \cdot \mathbf{x}), \quad (8.1)$$

with energy given by

$$E(k) = \frac{\mathbf{k} \cdot \mathbf{k}}{2m} \hbar^2. \quad (8.2)$$

The unitarity of time evolution guarantees conservation of probability. We say that given a wavefunction  $\psi(\mathbf{x}, t)$ , the quantity  $|\psi(\mathbf{x}, t)|^2$  gives the probability density to find the particle in the interval (region)  $[\mathbf{x}, \mathbf{x} + d\mathbf{x}]$ ,

$$\rho(\mathbf{x}, t) = |\psi(\mathbf{x}, t)|^2. \quad (8.3)$$

Unitarity says that

$$\psi(\mathbf{x}, t) = U(\mathbf{x}, t; \mathbf{x}', t') \psi(\mathbf{x}', t'). \quad (8.4)$$

Usually we just indicate the time dependence of  $U$ . Since  $UU^\dagger = \mathbb{I}$ , our probability integrated over some region  $D$  is

$$\int_D \rho(\mathbf{x}, t) d^d x = \int_D |\psi(\mathbf{x}, t)|^2 d^d x. \quad (8.5)$$

Notice now that

$$\frac{d}{dt} \int_D d^d x |\psi(\mathbf{x}, t)|^2 = \int_D d^d x \left( \psi^* \frac{\partial \psi}{\partial t} + \psi \frac{\partial \psi^*}{\partial t} \right) \quad (8.6)$$

$$= \int_D d^d x \left[ \psi^* \left( \frac{i\hbar}{2m} \nabla^2 - i\hbar V(\mathbf{x}) \right) \psi + \psi \left( -\frac{i\hbar}{2m} \nabla^2 + i\hbar V(\mathbf{x}) \right) \psi^* \right], \quad (8.7)$$

where in the third line we have just used Schrödinger's equation (or its complex conjugate) to replace the time derivatives. Now the potential terms cancel, since they are just multiplication by some numbers. What remains is

$$\frac{d}{dt} \int_D d^d x = \frac{i\hbar}{2m} \int_D d^d x (\psi^* \nabla^2 \psi - \psi \nabla^2 \psi^*) \quad (8.8)$$

$$= \frac{i\hbar}{2m} \int_D d^d x \nabla \cdot (\psi^* \nabla \psi - \psi \nabla \psi^*). \quad (8.9)$$

Defining a current, or *probability flux density*, by

$$\mathbf{J}(\mathbf{x}, t) = -\frac{i\hbar}{2m} (\psi^* \nabla \psi - \psi \nabla \psi^*), \quad (8.10)$$

we see that

$$\int_D d^d x \left( \frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{J} \right) = 0 \implies \frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{J} = 0. \quad (8.11)$$

This gives us a *local statement of probability conservation*. The probability to find the particle at some location generally changes in time, but the change in its probability is directly related to the divergence of the probability current. In integral form, the probability to find the particle in some region decreases by the flux of the probability current through the boundary of the region. For notice that

$$\int_D d^d x \nabla \cdot \mathbf{J} = \int_{\partial D} \mathbf{J} \cdot d\mathbf{S}. \quad (8.12)$$

Global conservation laws are true, but they are hard to impose because they require us to “sample” all of space. Local conservation laws are much more useful in deriving boundary conditions because we only need to check them point by point.

Now consider plane wave solutions,

$$\psi(\mathbf{x}, t) = A e^{i\mathbf{k} \cdot \mathbf{x}}. \quad (8.13)$$

Then the probability current is

$$\mathbf{J} = |A|^2 \frac{\hbar}{m} \mathbf{k}, \quad (8.14)$$

and we see that the probability flux for a momentum eigenstate is given by the momentum eigenvalue. That is, probability flows constantly in the  $\mathbf{k}$  direction and its divergence is zero.

**Example 8.15.** Consider now

$$\psi(\mathbf{x}, t) = A_1 e^{i\mathbf{k}_1 \cdot \mathbf{x}} + A_2 e^{i\mathbf{k}_2 \cdot \mathbf{x}}. \quad (8.16)$$

What do we think the probability current will be? We expect there will be pure  $\mathbf{k}_1, \mathbf{k}_2$  terms. But since this is a superposition, there will in general be interference terms:

$$\mathbf{J}(\mathbf{x}, t) = \frac{\hbar}{m} \left[ |A_1|^2 \mathbf{k}_1 + |A_2|^2 \mathbf{k}_2 + (\mathbf{k}_1 + \mathbf{k}_2) \{ \text{Re}(A_1 A_2^*) \cos((\mathbf{k}_1 - \mathbf{k}_2) \cdot \mathbf{x}) - \text{Im}(A_1 A_2^*) \sin((\mathbf{k}_1 - \mathbf{k}_2) \cdot \mathbf{x}) \} \right]. \quad (8.17)$$

The cross-terms represent interference.

Recall our 1D free particle time-dependent solution (wavepacket),

$$\psi(x, t) \propto \exp ik \left( x - \frac{k\hbar t}{2m} \right) - \frac{1}{2\delta_x^2 \left( 1 + \frac{i\hbar t}{m\delta_x^2} \right)} \left( x - \frac{k\hbar t}{m} \right)^2. \quad (8.18)$$

Its expected location is

$$\langle x(t) \rangle = \frac{1}{m} k\hbar t, \quad (8.19)$$

and its width is

$$\Delta x = \frac{1}{\sqrt{2}} \delta_x \sqrt{1 + \frac{\hbar^2 t^2}{m^2 \delta_x^4}}. \quad (8.20)$$

This drift in  $\langle x(t) \rangle$  comes from the probability flux. Where we are most likely to find the particle drifts and flows, but what is conserved is the area under the (square of the) wavefunction, which is normalized to 1.

**Tunneling under a barrier** Suppose we have a potential which looks like a step,

$$V(x) = \begin{cases} 0 & x < 0 \text{ or } x > a \\ V_0 & 0 \leq x \leq a. \end{cases} \quad (8.21)$$

In the left region  $x < 0$ , we have plane wave scattering states

$$\psi(x) = A_L e^{ikx} + B_L e^{-ikx}, \quad (8.22)$$

and similarly on the right,  $x > a$ ,

$$\psi(x) = A_R e^{ikx} + B_R e^{-ikx}. \quad (8.23)$$

By convention, we will take  $k$  to be positive so that the right-movers are  $e^{ikx}$  and the left-movers are  $e^{-ikx}$ . (Recall that the time dependence is  $e^{-iEt}$ , so the signs work out as we expect.) The energy of such a state is

$$E(k) = \frac{\hbar^2 k^2}{2m} < V_0. \quad (8.24)$$

That is, let us restrict ourselves to considering states which would classically just bounce off the potential barrier and could never make it through. We define

$$\alpha^2 = \frac{2m}{\hbar^2} (V_0 - E). \quad (8.25)$$

Then we claim that in the classically forbidden region ( $V_0 > E$ ), our solutions take the form

$$\psi(x) = C e^{\alpha x} + D e^{-\alpha x}. \quad (8.26)$$

For notice that in the barrier region, the Schrödinger equation takes the form

$$\left[ -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + V_0 \right] \psi(x) = E \psi(x) \implies \frac{\hbar^2}{2m} \frac{d^2}{dx^2} \psi(x) = (V_0 - E) \psi(x), \quad (8.27)$$

with  $V_0 - E > 0$ . This suggests that  $\psi$  will look like a sum of exponentials in this region, i.e.

$$\frac{d^2}{dx^2} \psi(x) = \alpha^2 \psi(x). \quad (8.28)$$

We can make some arguments now on physical grounds. Suppose we send in some wave coming from the left (i.e. right-moving) with energy  $E < V_0$ . We expect there will be some reflected (left-moving) wave in this region as well. Notice that for a 1D wavefunction

$$\psi(x, t) = A e^{ikx} + B e^{-ikx}, \quad (8.29)$$

the probability current (cf. Eqn 8.17) simplifies to

$$J(x, t) = \frac{\hbar}{m} (|A|^2 - |B|^2) k. \quad (8.30)$$

Now we cannot quite impose the Schrödinger equation at the boundary of the classically forbidden region, but we can demand that the probability current  $J$  is continuous along boundaries, and since

$$\mathbf{J}(\mathbf{x}, t) = -\frac{i\hbar}{2m} (\psi^* \nabla \psi - \psi \nabla \psi^*), \quad (8.31)$$

this tells us that  $\psi, \nabla \psi$  are therefore continuous across boundaries.<sup>40</sup> That is, we may write

$$\begin{aligned} \psi(x = 0^-) &= \psi(x = 0^+) & \psi(x = a^-) &= \psi(x = a^+) \\ \psi'(x = 0^-) &= \psi'(x = 0^+) & \psi'(x = a^-) &= \psi'(x = a^+). \end{aligned}$$

We'll write these boundary conditions in a funny way, as a matrix equation:

$$\underbrace{\begin{pmatrix} 1 & 1 \\ ik & -ik \end{pmatrix}}_{M_1} \underbrace{\begin{pmatrix} A_L \\ B_L \end{pmatrix}}_{M_2} = \underbrace{\begin{pmatrix} 1 & 1 \\ \alpha & -\alpha \end{pmatrix}}_{M_2} \underbrace{\begin{pmatrix} C \\ D \end{pmatrix}}_{M_3}, \quad \underbrace{\begin{pmatrix} e^{\alpha a} & e^{-\alpha a} \\ \alpha e^{\alpha a} & -\alpha e^{-\alpha a} \end{pmatrix}}_{M_3} \underbrace{\begin{pmatrix} C \\ D \end{pmatrix}}_{M_3} = \underbrace{\begin{pmatrix} e^{ika} & e^{-ika} \\ ike^{ika} & -ike^{-ika} \end{pmatrix}}_{M_4} \underbrace{\begin{pmatrix} A_R \\ B_R \end{pmatrix}}_{M_4}. \quad (8.32)$$

<sup>40</sup>This second claim is not quite true for e.g. delta function potentials. We'll come back to this loophole later.

Written more compactly,

$$M_1 \begin{pmatrix} A_L \\ B_L \end{pmatrix} = M_2 \begin{pmatrix} C \\ D \end{pmatrix}, \quad M_3 \begin{pmatrix} C \\ D \end{pmatrix} = M_4 \begin{pmatrix} A_R \\ B_R \end{pmatrix}, \quad (8.33)$$

so that with a bit of matrix manipulation to solve for  $\begin{pmatrix} A_L \\ B_L \end{pmatrix}$ , we find that

$$\begin{pmatrix} A_L \\ B_L \end{pmatrix} = M_1^{-1} M_2 M_3^{-1} M_4 \begin{pmatrix} A_R \\ B_R \end{pmatrix} = \mathcal{T} \begin{pmatrix} A_R \\ B_R \end{pmatrix}, \quad (8.34)$$

where  $\mathcal{T}$  is called the *transfer matrix*. Unfortunately, it is rather complicated:

$$\mathcal{T} = \begin{pmatrix} e^{ika} \left[ \cosh(\alpha a) + \frac{i}{2} \sin(\alpha a) \left( \frac{\alpha}{k} - \frac{k}{\alpha} \right) \right] & \frac{i}{2} e^{-ika} \sinh(\alpha a) \left( \frac{\alpha}{k} + \frac{k}{\alpha} \right) \\ -\frac{i}{2} e^{-ika} \sinh(\alpha a) \left( \frac{\alpha}{k} + \frac{k}{\alpha} \right) & e^{-ika} \left[ \cosh(\alpha a) - \frac{i}{2} \sin(\alpha a) \left( \frac{\alpha}{k} - \frac{k}{\alpha} \right) \right] \end{pmatrix} \quad (8.35)$$

Now suppose that we only send in a right-moving wave from  $x = -\infty$ , such that  $B_R = 0$ . That is, there is no incoming wave from  $x = +\infty$ . We would like to know the following:

- i) What is the reflected wave?
- ii) Is there transmission?

In the right region, the transmitted wave would have flux

$$|A_R|^2 \frac{\hbar k}{m} \quad (8.36)$$

since there is just the right-moving solution. In the left region, the incoming plus reflected wave give flux

$$\frac{\hbar k}{m} (|A_L|^2 - |B_L|^2). \quad (8.37)$$

If we define the transmission and reflection coefficients

$$T = \left| \frac{A_R}{A_L} \right|^2, \quad R = \left| \frac{B_L}{A_L} \right|^2, \quad (8.38)$$

then (total) flux conservation guarantees that

$$R + T = 1. \quad (8.39)$$

In fact, this innocuous-looking statement is the statement of unitarity. If we send in one particle, a “piece” of that particle comes back to you and a “piece” of that particle is transmitted through the barrier, at least at the level of probabilities.

In terms of the transfer matrix elements (which relate  $A_L, B_L, A_R$ ), we have

$$R = \left| \frac{\mathcal{T}_{21}}{\mathcal{T}_{11}} \right|^2, \quad T = \left| \frac{1}{\mathcal{T}_{11}} \right|^2, \quad (8.40)$$

and by plugging in we see that our transmission coefficient is

$$T = \left( 1 + \frac{V_0^2}{4E(V_0 - E)} \sinh^2(\alpha a) \right)^{-1} \approx \frac{4E(V_0 - E)}{V_0^2} e^{-2\frac{\sqrt{2m(V_0 - E)}}{\hbar} a} \quad (8.41)$$

for  $\alpha a \gg 1$ . We see that for very wide barriers (large  $a$ ) or very high barriers (large  $\alpha^2 \sim V_0 - E$ ), the probability of tunneling is exponentially suppressed.

Lecture 9.

**Thursday, October 24, 2019**

Last time, we discussed tunneling through a step potential. There were only scattering states and no bound states (normalizable states with vanishing probability at  $\infty$ ). The transmission is roughly proportional to the area under the barrier, as

$$T \propto e^{-2\alpha a}, \quad \alpha = \frac{\sqrt{2m(V_0 - E)}}{\hbar}. \quad (9.1)$$

So tall and/or wide barriers will suppress the transmission probability. Note also that for incoming waves with energy higher than the “step,”  $E - V_0 > 0$ , there is still a reflection probability as well as a transmission probability.

So far, we have discussed the bound states of the harmonic oscillator (a confining potential) as well as scattering states (plane wave states) for the free particle. Let us be more careful about what we mean here.

**Bound states** For potentials which are unbounded at spatial infinity, if

$$V(x) \rightarrow |x| \rightarrow \infty, \quad (9.2)$$

then the system has bound states such that

$$\lim_{x \rightarrow \pm\infty} \psi(x) = 0. \quad (9.3)$$

That is, a bound state is exponentially small outside of some finite region. On the other hand, a general system will generically have a mix of bound and scattering states. The classic example is an attractive  $\delta$ -function potential, where

$$V(x) = -V_0\delta(x). \quad (9.4)$$

For this potential, we have a Schrödinger equation

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} - V_0\delta(x)\psi(x) = E\psi(x). \quad (9.5)$$

We’ll come back to the scattering states; they are  $e^{ikx}$  as before. But there is exactly one bound state in this problem. And a scattering state has some probability to be trapped and become a bound state. This tells us there’s a nontrivial reflection coefficient.

Let’s see this explicitly. Consider the bound state(s), since scattering states exist with  $E > 0$ . How will we solve for the bound state? Let us make the ansatz that our bound state wavefunction must be exponentially damped as the particle goes to  $\pm\infty$ . That is, for  $|x| \rightarrow \pm\infty$ ,  $\psi$  takes the form

$$\psi(x) = \begin{cases} A_L e^{\kappa x} + B_L e^{-\kappa x} & x < 0 \\ A_R e^{\kappa x} + B_R e^{-\kappa x} & x > 0, \end{cases} \quad (9.6)$$

with

$$\kappa = \frac{\sqrt{2mE_b}}{\hbar}. \quad (9.7)$$

For notice that away from  $x = 0$ , the  $E < 0$  bound states have some  $E = -E_b$ ,  $E_b > 0$ , such that

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} = -E_b\psi, \quad (9.8)$$

and therefore the solutions are exponentials. Moreover,  $B_L = A_R = 0$  since we want our solutions to decay at infinity (normalizability). But it seems that  $A_L, B_R$  are underdetermined, as is  $E_b$ . We still need a boundary condition at  $x = 0$  (two, actually).

The boundary conditions are as follows:

- i)  $\psi(x)$  is continuous at the origin for probability flux to be conserved
- ii)  $\psi'(x)$  is not continuous; its discontinuity will depend on the integral over the delta-function potential.

Continuity immediately gives us that  $A_L = B_R$ , so

$$\psi(x) = \begin{cases} A_L e^{\kappa x} & x < 0 \\ A_L e^{-\kappa x} & x > 0, \end{cases} \quad (9.9)$$

Suppose now that we integrate the Schrödinger equation between  $x = -\epsilon$  and  $x = +\epsilon$ . Hence

$$\int_{-\epsilon}^{\epsilon} dx \left[ -\frac{\hbar^2}{2m} \psi''(x) - V_0\delta(x)\psi(x) \right] = -\int_{-\epsilon}^{\epsilon} dx E_b\psi(x). \quad (9.10)$$

The first term gives us

$$-\frac{\hbar^2}{2m} [\psi'(\epsilon) - \psi'(-\epsilon)] - V_0\psi(0) = -E_b O(\epsilon). \quad (9.11)$$

In the limit as  $\epsilon \rightarrow 0$ , we have

$$-\frac{\hbar^2}{2m}[\psi'(0^+) - \psi'] - V_0\psi(0) = 0. \quad (9.12)$$

If we plug in our ansatz for  $\psi(x)$ , we get

$$-\frac{\hbar^2}{2m}[A_L(-\kappa) - A_L(\kappa)] - V_0A_L = 0, \quad (9.13)$$

which tells us that

$$\kappa = \frac{m}{\hbar^2}V_0. \quad (9.14)$$

This tells us the bound state energy:

$$\kappa = \frac{\sqrt{2mE_b}}{\hbar} \implies E_B = \frac{m}{2\hbar^2}V_0. \quad (9.15)$$

If we fix the normalization of  $\psi$  to be  $\int_{-\infty}^{\infty} |\psi|^2 dx = 1$ , we can uniquely determine  $A_L$ :

$$\psi(x) = \begin{cases} \sqrt{\kappa}e^{\kappa x} & x < 0 \\ \sqrt{\kappa}e^{-\kappa x} & x > 0. \end{cases} \quad (9.16)$$

This has interesting physical consequences. For instance, it is responsible for the phenomenon of Anderson localization, where defects in metal disrupt the conductivity of that metal because they force the electron wavefunction to become localized and therefore not free. Note that many-particle systems are different, though. The Anderson localization of many-particle systems violates the “eigenstate thermalization hypothesis,” producing unusual interference that destroys conductivity.

For a homework problem, we will consider the transmission and reflection coefficients for a scattering state; the wavefunction is still continuous but the discontinuity in the derivative is defined by the integral of the potential over a vanishingly small region. The scattering will be nontrivial.

What about a finite rectangular well? In such a case, we will have scattering states, but the existence of bound states depends both on the width and height of the well. Bound states have some minimum energy, analogous to the ground state of the infinite square well, so the well must be some minimum depth in order to support bound states.

Note— what if we take the potential to be a derivative of a delta function,  $V(x) = -V_0\delta^{(n)}(x)$ ? The limit is apparently well-defined but the direct solution is not obvious because the discontinuity in the derivative is also apparently infinite. We can integrate the  $\delta$ -function term by parts, but it relates the derivative discontinuity to higher derivatives at the origin, which seems ill-defined.<sup>41</sup>

**Periodic potentials in 1D** Suppose we have a periodic potential with

$$V(x+a) = V(x), \quad (9.17)$$

i.e. it obeys the symmetry of  $x \rightarrow x + na, n \in \mathbb{Z}$ . This is a bit like a 1D lattice.

**Claim** (Bloch’s theorem (Floquet)). Wavefunctions solving periodic potentials with period  $a$  take the form

$$\psi(x) = e^{iKx}\phi_K(x), \quad (9.18)$$

where

$$\phi_K(x) = \phi_K(x+a), \quad (9.19)$$

where  $K$  is called the Bloch momentum and can be taken to lie in the range  $-\pi/a \leq K \leq \pi/a$ .

That is, the momenta lie in one block of the dual (Fourier-transformed) lattice. This is tantamount to solving the problem on a circle and then arguing that distinct solutions correspond to shifts up to the circle periodicity. Equivalently, an individual solution for the wavefunction is itself periodic up to an overall phase. More generally we will get superpositions of various Bloch momenta  $K$ .

We claim that while our problem does not have a continuous symmetry, we can take advantage of the discrete translational symmetry of the lattice. That is, there will be a generator of discrete translations that commutes with the Hamiltonian.

<sup>41</sup>It took Mukund “two minutes” this morning to decide he could not make immediate progress with this problem.

**Example 9.20** (Dirac comb). Let us take a potential of this form,

$$V(x) = \frac{\hbar^2}{2m} V_0 \sum_{n=-\infty}^{\infty} \delta(x + na). \quad (9.21)$$

Look at it over the interval  $x \in [0, a]$ . In such an interval we have free particles,

$$\phi_1 = e^{ikx}, \quad \phi_2 = e^{-ikx}, \quad (9.22)$$

which form linearly independent solutions to the Schrödinger equation. Hence

$$\psi(x) = \alpha_1 e^{ikx} + \alpha_2 e^{-ikx}, \quad 0 \leq x \leq a. \quad (9.23)$$

Then Bloch's theorem says that in the next interval  $a \leq x \leq 2a$ , the wavefunction is

$$\psi(x) = e^{iKa} \left( \alpha_1 e^{ik(x-a)} + \alpha_2 e^{-ik(x-a)} \right). \quad (9.24)$$

We can now impose the boundary conditions. A priori we have four unknowns:  $\alpha_1, \alpha_2, k, K$ . At  $x = a$ , the wavefunction is continuous,

$$\psi(x = a^-) = \psi(x = a^+), \quad (9.25)$$

but its derivative is not,

$$\psi'(x = a^+) = \psi'(x = a^-) + 2V_0\psi(a). \quad (9.26)$$

We get this discontinuity from the same sort of procedure as before, but with a sign flip because the potential is repulsive, not attractive.

Plugging in the wavefunctions, we see that

$$\alpha_1 e^{ika} + \alpha_2 e^{-ika} = e^{iKa} (\alpha_1 + \alpha_2) \quad (9.27)$$

$$ike^{iKa} (\alpha_1 - \alpha_2) = ik(\alpha_1 e^{ika} - \alpha_2 e^{-ika}) + 2V_0(\alpha_1 e^{ika} + \alpha_2 e^{-ika}). \quad (9.28)$$

This can now be written as a matrix equation on the coefficients  $\alpha_1, \alpha_2$  of the form  $A\alpha = 0$ , and the coefficient matrix  $A$  should have vanishing determinant (is non-invertible) in order to get a nontrivial solution for  $\alpha$ . Using this condition, one finds that

$$\cos Ka = \cos ka + \frac{V_0}{k} \sin ka. \quad (9.29)$$

Notice that the LHS is bounded by  $\pm 1$  because of the range of  $K$ . This tells us that  $k$  is not totally arbitrary. For a wavefunction to exist, the RHS must also be bounded:

$$\left| \cos ka + \frac{V_0}{k} \sin ka \right| \leq 1, \quad (9.30)$$

and  $E = \frac{\hbar^2 k^2}{2m}$ . Solving this for the allowed values of  $k$  will give us energy bands with gaps in between, and this is the origin of electronic band structure.

Lecture 10.

**Tuesday, October 29, 2019**

Logistic note— there is a more challenging homework up this week. The first problem asks us to reason physically about the solutions to a harmonic oscillator with a delta function perturbation. There's also a nice bonus problem to do with the Poschl-Teller potentials.

Let us now derive Bloch's (Floquet's) theorem, which we saw an application of last time. Recall the statement of Bloch's theorem was that the solutions of periodic potentials can be composed of wavefunctions which are also periodic (with the same period) up to a phase.<sup>42</sup>

That is, take  $V(x)$  such that

$$V(x + a) = V(x), \quad x \rightarrow x + na, n \in \mathbb{Z}. \quad (10.1)$$

<sup>42</sup>Equivalently, we can simultaneously diagonalize the Hamiltonian and the discrete translation operator. This is how it is described in Griffiths.

Say that  $\phi_1(x), \phi_2(x)$  are 2 l.i. solutions to

$$\left[ -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + V(x) \right] \phi(x) = E\phi(x). \quad (10.2)$$

Then  $\phi_1(x+a), \phi_2(x+a)$  are also solutions— just shift the arguments, and the potential shifts with it. But  $\phi_1, \phi_2$  were linearly independent, so the shifted versions must be linear combinations of the original solutions:

$$\phi_1(x+a) = \alpha_{11}\phi_1(x) + \alpha_{12}\phi_2(x) \quad (10.3)$$

$$\phi_2(x+a) = \alpha_{21}\phi_1(x) + \alpha_{22}\phi_2(x). \quad (10.4)$$

If  $\psi(x)$  is some such linear combination, then there exists a choice of coefficients such that

$$\psi(x+a) = \lambda\psi(x), \lambda \in \mathbb{C}, |\lambda| = 1. \quad (10.5)$$

In mathematics this is called Floquet's theorem. We can prove this—

$$\psi(x) = A\phi_1(x) + B\phi_2(x) \quad (10.6)$$

$$\begin{aligned} \psi(x+a) &= A\phi_1(x+a) + B\phi_2(x+a) \\ &= A[\alpha_{11}\phi_1(x) + \alpha_{12}\phi_2(x)] + B[\alpha_{21}\phi_1(x) + \alpha_{22}\phi_2(x)]. \end{aligned} \quad (10.7)$$

Now if we suppose that

$$\psi(x+a) = \lambda\psi(x) = \lambda[A\phi_1(x) + B\phi_2(x)], \quad (10.8)$$

then by comparison to our expansion 10.7 we see that

$$A\alpha_{11} + B\alpha_{21} = \lambda A \quad (10.9)$$

$$A\alpha_{12} + B\alpha_{22} = \lambda B. \quad (10.10)$$

The statement this equation has solutions (that the matrix of  $\alpha$ s has eigenvalues) is equivalent to the statement that

$$\det \begin{pmatrix} \alpha_{11} - \lambda & \alpha_{21} \\ \alpha_{12} & \alpha_{22} - \lambda \end{pmatrix} = 0. \quad (10.11)$$

The coefficients  $\alpha_{ij}$  are fixed by the properties of  $\phi_1, \phi_2$ . That means we have a quadratic equation for  $\lambda$  which has 2 roots  $\lambda_1, \lambda_2$ .<sup>43</sup> We therefore have wavefunctions  $\psi_1, \psi_2$  such that

$$\psi_1(x+a) = \lambda_1\psi_1(x), \quad \psi_2(x+a) = \lambda_2\psi_2(x). \quad (10.12)$$

To show these lambdas are of unit norm,  $|\lambda_1| = |\lambda_2| = 1$ , we need something else. In particular, we need to use normalizability and also prove that  $\lambda_1\lambda_2 = 1$ . The first part is easier. Notice that

$$\psi_i(x+na) = \lambda_i^n \psi_i(x). \quad (10.13)$$

This suggests that if  $|\lambda| \neq 1$ , then the wavefunction value grows arbitrarily large as  $x$  increases to  $\pm\infty$ , which breaks normalizability. We conclude that  $|\lambda_1| = |\lambda_2| = 1$ .

For the second fact, consider the Wronskian<sup>44</sup>

$$W(x) = \psi_1(x)\psi_2'(x) - \psi_1'(x)\psi_2(x). \quad (10.14)$$

It follows from Eqn. 10.12 that

$$W(x+a) = \lambda_1\lambda_2 W(x). \quad (10.15)$$

But the Wronskian is in fact constant,  $W'(x) = 0$ , by Schrödinger's equation.<sup>45</sup> Hence

$$W(x+a) = W(x) \implies \lambda_1\lambda_2 = 1. \quad (10.16)$$

<sup>43</sup>Note that the matrix of  $\alpha$ s is actually unitary by probability conservation. This is sufficient to let us diagonalize the matrix of  $\alpha$ s, i.e. we can indeed solve for the roots  $\lambda_1, \lambda_2$ .

<sup>44</sup>For a refresher on the Wronskian, see my 204A notes. It tests linear (in)dependence.

<sup>45</sup>This is generally true for two linearly independent solutions to a second-order equation. Taking the derivative, the cross-terms like  $\psi_1'\psi_2'$  cancel, and the other terms like  $\psi_1''\psi_2$  cancel after we replace second derivatives with their expressions in terms of the original functions.

Combining these two facts we see that

$$\lambda_1 = e^{iKa}, \lambda_2 = e^{-iKa}, \quad (10.17)$$

where  $K$  is a real parameter, and WLOG we can restrict

$$-\frac{\pi}{a} \leq K \leq \frac{\pi}{a} \quad (10.18)$$

where  $a$  was the period of the potential. Hence we can find solutions to periodic potentials such that

$$\psi(x+a) = e^{\pm iK(x+a)} \phi_K(x+a) = e^{\pm iKa} \psi(x). \quad (10.19)$$

**Theorem 10.20** (Bloch). *For  $V(x) = V(x+na), n \in \mathbb{Z}$ , there exist solutions*

$$\psi(x) = e^{\pm iKx} \phi_K(x), \quad \phi_K(x) = \phi_K(x+a). \quad (10.21)$$

Notice we haven't actually solved the Schrödinger equation yet; we've just said that its solutions can be expressed as linear combinations of wavefunctions which are periodic up to a phase. To find energy eigenvalues, take

$$\psi(x) = A\phi_1(x) + B\phi_2(x), \quad 0 \leq x \leq a. \quad (10.22)$$

That is, it is a linear combination of the basis solutions between 0 and  $a$ . We assume nothing about the periodicity of  $\phi_1$  and  $\phi_2$ . Hence in the next unit cell, it is given by

$$\psi(x) = e^{iKa} [A\phi_1(x-a) + B\phi_2(x-a)], \quad a \leq x \leq 2a, \quad (10.23)$$

where we have just pulled out the overall phase. Continuity of  $\psi$  and its derivative at  $a$ <sup>46</sup> gives

$$A\phi_1(a) + B\phi_2(a) = e^{iKa} [A\phi_1(0) + B\phi_2(0)], \quad (10.24a)$$

$$A\phi_1'(a) + B\phi_2'(a) = e^{iKa} [A\phi_1'(0) + B\phi_2'(0)]. \quad (10.24b)$$

For a solution to  $A$  and  $B$  to exist, the matrix of coefficients must have zero determinant,

$$\det \begin{pmatrix} \phi_1(a) - e^{iKa}\phi_1(0) & \phi_2(a) - e^{iKa}\phi_2(0) \\ \phi_1'(a) - e^{iKa}\phi_1'(0) & \phi_2'(a) - e^{iKa}\phi_2'(0) \end{pmatrix} = 0. \quad (10.25)$$

We can solve this to find

$$\cos Ka = \frac{1}{2W[\phi_1, \phi_2]} [(\phi_1(0)\phi_2'(a) + \phi_1(a)\phi_2'(0)) - (\phi_2(0)\phi_1'(a) + \phi_2(a)\phi_1'(0))], \quad (10.26)$$

with  $W[\phi_1, \phi_2]$  the Wronskian, evaluated at any point in the interval  $[0, a]$ . Recall it is nonvanishing for any linearly independent functions  $\phi_1, \phi_2$ . We see that this justifies why we restricted  $K$  to lie in  $[-\pi/2, \pi/2]$ . Moreover, we will generally get certain ranges of  $K$  which are allowed and some which are forbidden. This gives rise to a *band structure*, which is a key idea in condensed matter physics, and we saw our first hint of this in the Dirac comb.

It is a remarkable fact that  $k$ -space can have a nontrivial topology when we consider the bands of allowed values of  $k$  in three-dimensional materials. This is closely related to the phenomenon of topological insulators.

To conclude this class, let us discuss some properties of single-particle wavefunctions.

- Ground state wavefunctions do not have nodes, i.e.  $\psi(x) \neq 0$  anywhere on the open interval. A rough proof is as follows—suppose our wavefunction has a zero. Then we can construct another function (not necessarily a solution to the Schrödinger equation) which has a lower energy (expectation value of the Hamiltonian), which tells us that the original wavefunction must not have been the ground state.<sup>47</sup> This fact is also true in higher dimensions than 1.
- The energy spectrum for bound state wavefunctions in 1D (one spatial dimension) is nondegenerate. The proof is by contradiction—suppose two distinct states of the same energy exist, and then show they must in fact be proportional to each other.

<sup>46</sup>The latter is not true for the Dirac comb because of the delta functions.

<sup>47</sup>This sounds like an example of the variational principle. Anyway, the proof is in the notes. This statement will also be important for the homework.

**Thursday, October 31, 2019**

Today we will introduce density matrices, a different formalism for describing quantum states.

To begin with, consider what makes quantum mechanics so quantum. One answer is the uncertainty principle, which reflects the non-commuting nature of various observables in our theory. However, we will argue that the quantum-ness of QM is in fact better-represented by the phenomenon of entanglement.

That is, the uncertainty principle

$$\Delta x \Delta p \geq \frac{\hbar}{2} \quad (11.1)$$

is simply a consequence of operator non-commutativity. More generally if  $A, B$  are non-commuting then

$$(\Delta A)^2 (\Delta B)^2 \geq \left( \frac{i}{2} \langle [A, B] \rangle \right)^2. \quad (11.2)$$

Let us prove this.

*Proof.* For (non-commuting Hermitian) operators  $A$  and  $B$ , consider

$$\tilde{A} = A - \langle \psi | A | \psi \rangle, \quad (11.3)$$

$$\tilde{B} = B - \langle \psi | B | \psi \rangle \quad (11.4)$$

for some state  $|\psi\rangle$ . Hence

$$(\Delta A)^2 = \langle \psi | \tilde{A}^2 | \psi \rangle, \quad (\Delta B)^2 = \langle \psi | \tilde{B}^2 | \psi \rangle. \quad (11.5)$$

Since  $\tilde{A}, \tilde{B}$  are just shifted versions of  $A$  and  $B$ , it follows that

$$[\tilde{A}, \tilde{B}] = [A, B]. \quad (11.6)$$

Let us consider some new states  $|\tilde{\psi}_\lambda\rangle$  defined by

$$|\tilde{\psi}_\lambda\rangle \equiv (\tilde{A} + i\lambda\tilde{B})|\psi\rangle, \quad \lambda \in \mathbb{R}. \quad (11.7)$$

As all such  $|\tilde{\psi}_\lambda\rangle$  are in the Hilbert space,

$$\langle \tilde{\psi}_\lambda | \tilde{\psi}_\lambda \rangle \geq 0 \quad (11.8)$$

and expanding, we have

$$0 \leq \langle \psi | (\tilde{A}^\dagger - i\lambda\tilde{B}) (\tilde{A} + i\lambda\tilde{B}) | \psi \rangle \quad (11.9)$$

$$\leq \langle \psi | \tilde{A}^2 | \psi \rangle + \lambda^2 \langle \psi | \tilde{B}^2 | \psi \rangle + i\lambda \langle \psi | [\tilde{A}, \tilde{B}] | \psi \rangle \quad (11.10)$$

$$\leq (\Delta A)^2 + \lambda^2 (\Delta B)^2 + i\lambda \langle [A, B] \rangle. \quad (11.11)$$

Note that the commutator of  $A, B$  is *antihermitian*, so its eigenvalues are imaginary. This must hold for any  $\lambda \in \mathbb{R}$ , so in particular it holds for the  $\lambda$  that extremizes the inequality. Taking a derivative with respect to  $\lambda$  gives

$$\frac{d}{d\lambda} \left[ (\Delta A)^2 + \lambda^2 (\Delta B)^2 + i\lambda \langle [A, B] \rangle \right] = 0 \implies 2\lambda_* (\Delta B)^2 + i \langle [A, B] \rangle = 0, \quad (11.12)$$

and therefore

$$\lambda_* = -\frac{i}{2} \frac{\langle [A, B] \rangle}{(\Delta B)^2} \quad (11.13)$$

extremizes the inequality. If we plug in this value  $\lambda_*$  back into our inequality we find that

$$\langle \tilde{\psi}_{\lambda_*} | \tilde{\psi}_{\lambda_*} \rangle = (\Delta A)^2 + \frac{1}{4} \frac{(\langle [A, B] \rangle)^2}{(\Delta B)^2} \geq 0, \quad (11.14)$$

which after rearranging is the generalized uncertainty principle.  $\square$

**Density matrices** Having discussed the uncertainty principle, let us consider now what the defining property of quantum mechanics is. What makes it fundamentally different from classical systems? There are two ways to tackle this. One is to show that quantum probability distributions are intrinsically different from classical probability distributions. We'll do this later. But another good way to understand this is through the idea of density matrices (sometimes density operators or state operators), a different formalism for quantum ensembles.

Thus far, we have discussed state vectors  $|\psi\rangle$ . Recall the corresponding projection operators

$$\mathcal{P}_n = |z_n\rangle\langle z_n| \quad (11.15)$$

which project onto the state vector  $|z_n\rangle$ . That is,

$$\mathcal{P}_n|\psi\rangle = \langle z_n|\psi\rangle|z_n\rangle. \quad (11.16)$$

This suggests that instead of thinking of the vector in Hilbert space, we can think of the corresponding projector  $\mathcal{P}_n$ , which belongs to the space of operators, i.e.  $\mathcal{P}_n \in \mathcal{H} \otimes \mathcal{H}^*$ . That is, we identify<sup>48</sup>

$$|\psi\rangle \leftrightarrow |\psi\rangle\langle\psi|. \quad (11.17)$$

Now let us define the following.

**Definition 11.18.** A state/density operator, traditionally denoted as  $\rho$ , is an operator associated to a state which has three properties:

- (a) Positivity (i.e.  $\rho \geq 0$ , in the sense that its eigenvalues are non-negative and therefore  $\langle\psi|\rho|\psi\rangle \geq 0$ )<sup>49</sup>
- (b) Hermiticity ( $\rho^\dagger = \rho$ )
- (c) Normalization ( $\text{Tr}(\rho) = 1$ ).

Let us say what we mean by the trace of  $\rho$ . In a (pure) state  $\rho = |\psi\rangle\langle\psi|$ , we have

$$\begin{aligned} \text{Tr}(\rho) &= \text{Tr}(|\psi\rangle\langle\psi|) \\ &= \sum_n \langle e_n|\psi\rangle\langle\psi|e_n\rangle \\ &= \sum_n \langle\psi|e_n\rangle\langle e_n|\psi\rangle \\ &= \langle\psi|\left(\sum_n |e_n\rangle\langle e_n|\right)|\psi\rangle \\ &= \langle\psi|\mathbb{I}|\psi\rangle = \langle\psi|\psi\rangle. \end{aligned} \quad (11.19)$$

Hence if the original state was normalized, then its density matrices ought to be normalized.

Since  $\rho$  is hermitian, it has a spectral decomposition,

$$\rho = \sum_i p_i |\psi_i\rangle\langle\psi_i|, \quad (11.20)$$

where the  $|\psi_i\rangle$ s are eigenvectors of  $\rho$ , i.e.

$$\rho|\psi_i\rangle = p_i|\psi_i\rangle. \quad (11.21)$$

Then positivity implies  $p_i \geq 0$  and hermiticity implies  $p_i = p_i^*$ .<sup>50</sup> The normalization condition implies  $\sum_i p_i = 1$ .

The last thing we need is a rule to compute expectation values, and it is

$$\langle A \rangle = \text{Tr}(\rho A). \quad (11.22)$$

For notice that

$$\text{Tr}(\rho A) = \text{Tr}(|\psi\rangle\langle\psi| A) = \langle\psi|A|\psi\rangle = \langle A \rangle. \quad (11.23)$$

So this rule agrees on the simple class of density matrices for state  $\rho = |\psi\rangle\langle\psi|$ .

Hence we can define the evolution of the density matrix in time:

$$\rho(t) = |\psi(t)\rangle\langle\psi(t)| = U(t; t_0) |\psi(t_0)\rangle\langle\psi(t_0)| U(t; t_0)^\dagger = U(t; t_0) \rho(t_0) U(t; t_0)^\dagger. \quad (11.24)$$

<sup>48</sup>Formally the operator is an endomorphism, i.e. a map  $\mathcal{H} \rightarrow \mathcal{H}$ , but we won't use this language much.

<sup>49</sup>Strictly it is positive semi-definite.

<sup>50</sup>Hermiticity is kind of logically prior here. It doesn't make much sense to talk about complex eigenvalues being positive.

Notice this is different from how other operators transformed in the Heisenberg picture (as  $U^\dagger AU$ ). This tells us that what we've written down should really be interpreted as a Schrödinger picture *state operator*. Although the density matrix is an operator, this describes the time evolution of a state.

**Pure states and mixed states** Let us now discuss the difference between *pure states* and *mixed states*.

**Definition 11.25.** Pure states have density operators that are pure projectors. That is, they correspond to a single state we can write down as a vector in the Hilbert space,

$$\rho = |\psi\rangle\langle\psi|. \quad (11.26)$$

Equivalently, the spectral decomposition has one nonvanishing eigenvalue  $p_1 = 1$ , and its value is fixed by normalization. Hence

$$\rho^2 = \rho. \quad (11.27)$$

A weaker condition that is sometimes useful to test for purity is<sup>51</sup>

$$\text{Tr}(\rho^2) = 1. \quad (11.28)$$

In contrast, there are *mixed states*.

**Definition 11.29.** *Mixed states* are density operators that are convex combinations of pure states.

That is,  $\rho$  has a general spectral decomposition

$$\rho = \sum_i p_i \rho_i^{\text{pure}}, \quad 0 \leq p_i \leq 1. \quad (11.30)$$

This is the general form of a density operator, and it describes an ensemble of pure states  $\rho_i^{\text{pure}}$  with given probabilities  $p_i$ . Density matrices are statistical mixtures of pure states, so that when we compute an expectation value on a general density matrix, we get

$$\langle A \rangle = \text{Tr}(\rho A) \quad (11.31)$$

$$= \sum_i p_i \text{Tr}(\rho_i^{\text{pure}} A) \quad (11.32)$$

$$= \sum_i p_i \langle \psi_i | A | \psi_i \rangle. \quad (11.33)$$

That is, we compute the expectation values on the pure states and then we take a classical average weighted by the classical probabilities  $p_i$ .

For mixed states,

$$\text{Tr}(\rho^2) \leq 1. \quad (11.34)$$

Moreover, one can define an entropy, the *von Neumann entropy*, by

$$S = -\text{Tr}(\rho \log \rho). \quad (11.35)$$

The log of an operator is defined by the spectral decomposition of  $\rho$ . If  $\rho$  is diagonal as a matrix, then

$$S = -\sum p_i \ln p_i, \quad (11.36)$$

the Shannon entropy of the classical probability distribution  $\{p_i\}$ .<sup>52</sup>

Let us consider a qubit Hilbert space spanned by the state vectors  $\{|0\rangle, |1\rangle\}$ . It describes a state in  $\mathbb{C}^2$ . In fact, let us consider a 2-qubit Hilbert space,

$$\mathcal{H}_{\text{qubit}_1} \otimes \mathcal{H}_{\text{qubit}_2}. \quad (11.37)$$

This is a four-dimensional space<sup>53</sup> with basis

$$|0\rangle \otimes |0\rangle, |0\rangle \otimes |1\rangle, |1\rangle \otimes |0\rangle, |1\rangle \otimes |1\rangle. \quad (11.38)$$

We sometimes write this as

$$|00\rangle, |01\rangle, |10\rangle, |11\rangle \quad (11.39)$$

<sup>51</sup>The product of two density matrices is not always a density matrix! In general it is not.

<sup>52</sup>For more on quantum information, check out my Quantum Information notes on GitHub at <https://github.com/qmch/partiii-lecture-notes-201819>.

<sup>53</sup>Counting complex dimensions.

omitting the tensor products. The general density operator on a 2-qubit Hilbert space is then a  $4 \times 4$  matrix, such that there is a sum of operators

$$\rho = a_1 |00\rangle\langle 00| + a_2 |00\rangle\langle 01| + a_3 |00\rangle\langle 10| + a_4 |00\rangle\langle 11| + \dots + a_{13} |11\rangle\langle 00| + \dots + a_{16} |11\rangle\langle 11|. \quad (11.40)$$

Consider something simpler, the EPR state

$$\frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) = |\text{EPR}\rangle. \quad (11.41)$$

This is a pure state in the 2-qubit Hilbert space. Suppose we want to compute an operator acting only on the first qubit,

$$\langle A_1 \otimes \mathbb{I}_2 \rangle_{\text{EPR}}. \quad (11.42)$$

Then

$$\langle \text{EPR} | A_1 \otimes \mathbb{I}_2 | \text{EPR} \rangle = \text{Tr}(|\text{EPR}\rangle\langle \text{EPR}| (A_1 \otimes \mathbb{I}_2)) \quad (11.43)$$

$$= \text{Tr}_1(\rho_1 A_1), \quad (11.44)$$

where we claim this is now the expectation value in terms of a *reduced density matrix*  $\rho_1$ . We claim that  $\rho_1$  is a mixed state, where

$$\rho_1 = \text{Tr}_2(|\text{EPR}\rangle\langle \text{EPR}|). \quad (11.45)$$

Here, the subscripts now indicate *partial traces*. Notice that the density operator of the EPR state has four terms,

$$\begin{aligned} |\text{EPR}\rangle\langle \text{EPR}| &= \frac{1}{2}(|00\rangle + |11\rangle)(\langle 00| + \langle 11|) \\ &= \frac{1}{2}(|00\rangle\langle 00| + |00\rangle\langle 11| + |11\rangle\langle 00| + |11\rangle\langle 11|). \end{aligned}$$

Hence we can rewrite the overall trace as two partial traces,

$$\text{Tr}_{1 \otimes 2}(|\text{EPR}\rangle\langle \text{EPR}| (A_1 \otimes \mathbb{I}_2)) = \text{Tr}_1[\text{Tr}_2(|\text{EPR}\rangle\langle \text{EPR}| (A_1 \otimes \mathbb{I}_2))] \quad (11.46)$$

$$= \text{Tr}_1[\langle 0_2 | (|\text{EPR}\rangle\langle \text{EPR}| (A_1 \otimes \mathbb{I}_2)) | 0_2 \rangle + \langle 1_2 | (|\text{EPR}\rangle\langle \text{EPR}| (A_1 \otimes \mathbb{I}_2)) | 1_2 \rangle] \quad (11.47)$$

$$= \text{Tr}_1 \left[ \frac{1}{2} |0_1\rangle\langle 0_1| A_1 + \frac{1}{2} |1_1\rangle\langle 1_1| A_1 \right] = \text{Tr}_1(\rho_1 A_1), \quad (11.48)$$

where

$$\rho_1 = \frac{1}{2}(|0\rangle\langle 0| + |1\rangle\langle 1|). \quad (11.49)$$

Notice that the reduced state  $\rho_1$  is now a mixed state.

Lecture 12.

**Tuesday, November 5, 2019**

Last time, we introduced the idea of density matrices, and we suggested that it might be more useful to discuss not state vectors  $|\psi\rangle$  but generally state operators  $|\psi\rangle\langle\psi|$ , since a density matrix  $\rho$ , i.e. a positive, normalized, Hermitian operator, is the general state of a quantum system.

We explicitly showed that for a state vector in a composite system

$$|\text{EPR}\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) \in \mathcal{H}_{\text{qubit}} \otimes \mathcal{H}_{\text{qubit}}, \quad (12.1)$$

we could trace out the second qubit to get a reduced state  $\rho_1$ , namely

$$\rho_1 = \frac{1}{2}(|0\rangle\langle 0| + |1\rangle\langle 1|). \quad (12.2)$$

This state is mixed; it has equal probability of being in the  $|0\rangle$  state or being in the  $|1\rangle$  state. That is, the trace is the process of forgetting about qubit 2 (being agnostic to its state) and constructing a state in  $\mathcal{H}_1$

the first qubit state such that observables  $A$  measured only on qubit 1 will be consistent with the composite observable  $A \otimes \mathbb{I}$  measured on the two-qubit system. In particular, its entropy is

$$S_1 = \ln 2. \quad (12.3)$$

Let's pick  $|00\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$ . If we trace out qubit 2, now we have

$$\rho_1 = \text{Tr}_2(|00\rangle\langle 00|) = |0\rangle\langle 0|, \quad (12.4)$$

and we can also compute the von Neumann entropy of this reduced state. It is

$$S_1 = -1 \ln 1 = 0. \quad (12.5)$$

This is different from the EPR state. The  $|EPR\rangle$  state is a pure state of 2 qubits, but it has *non-trivial* correlations between qubits 1 and 2. Moreover, these are quantum correlations, not classical correlations. The presence of quantum correlations is quantum entanglement. That is, the  $|EPR\rangle$  state is a pure entangled state, whereas the state  $|00\rangle$  is a pure unentangled (product) state.

Recall that a pure state corresponds to a state vector in Hilbert space. It is a density operator with a single nonzero eigenvalue in its spectral decomposition. Equivalently,  $\rho^2 = \rho$ . We can also check that  $S(\rho) = -\text{Tr}(\rho \log \rho) = 0$ .

Conversely, mixed states are not pure. That is, they fail these properties:  $S(\rho) \neq 0$ ,  $\text{Tr}(\rho^2) < 1$ ,  $\rho^2 \neq \rho$ . Equivalently  $\rho_{ij} = \langle e_i | \rho | e_j \rangle$  has more than one non-zero eigenvalue.

**Entanglement** To discuss entanglement, we must work in a composite system. It is easiest to define entanglement by explaining what entanglement is not. A pure state of a composite system with no correlation between the components is called *separable*. Such states are tensor products of states in each component (i.e. the individual Hilbert space). They have the form

$$|\Psi\rangle = |\psi_1\rangle \otimes |\psi_2\rangle, \quad |\psi_i\rangle \in \mathcal{H}_i. \quad (12.6)$$

For instance,

$$|00\rangle = |0\rangle \otimes |0\rangle \text{ is separable.} \quad (12.7)$$

But

$$|00\rangle + |01\rangle + |10\rangle + |11\rangle \text{ is also separable,} \quad (12.8)$$

since this state is just  $(|0\rangle + |1\rangle) \otimes (|0\rangle + |1\rangle)$ . Separable states  $\implies$  unentangled.

Notice that if we construct the density matrix for such a state and trace out one component, then the reduced state is pure. (This implies that the entropy of the subsystem is zero.)

$$\text{Tr}_2((|\psi_1\rangle \otimes |\psi_2\rangle)(\langle\psi_1| \otimes \langle\psi_2|)) = |\psi_1\rangle\langle\psi_1| \langle\psi_2|\psi_2\rangle = |\psi_1\rangle\langle\psi_1|. \quad (12.9)$$

Now pure *entangled states* are just pure states that are not separable. Such states are (a subset of) linear combinations of separable states. For instance, the EPR state is a combination of two individually separable states  $|00\rangle$  and  $|11\rangle$ . Similarly there are other Bell (EPR) states like

$$\frac{1}{\sqrt{2}}(|01\rangle \pm |10\rangle), \quad \frac{1}{\sqrt{2}}(|00\rangle \pm |11\rangle). \quad (12.10)$$

Not all linear combinations of separable states are entangled. For instance,

$$|00\rangle + |01\rangle = |0\rangle \otimes (|0\rangle + |1\rangle) \quad (12.11)$$

is separable. The real way to tell is by taking the partial trace. *The partial trace of a separable state is a pure state. The partial trace of an entangled state is a mixed state.*

That is, if  $|\Psi\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$  is a (pure) entangled state, then

$$\rho_1 = \text{Tr}_2(|\Psi\rangle\langle\Psi|) \text{ and } \rho_2 = \text{Tr}_1(|\Psi\rangle\langle\Psi|) \quad (12.12)$$

are mixed states.<sup>54</sup>

Note that the subsystem entropies are equal:

$$S_1 = -\text{Tr}(\rho_1 \log \rho_1) = S_2 = -\text{Tr}(\rho_2 \log \rho_2). \quad (12.13)$$

---

<sup>54</sup>They are operators, so they formally belong to the space of endomorphisms on  $\mathcal{H}_1$  and  $\mathcal{H}_2$ . In particular they are not in the Hilbert spaces!

If after tracing out part of a state  $|\Psi\rangle$  we find that the subsystem entropy  $S_1 = S_2 = 0$ , then the original state was separable.

We might be interested in the question of whether a general mixed state can always be purified, i.e. whether it can be written as the partial trace of a bigger system. The answer is yes, but not uniquely. For

$$\rho_1 = \frac{1}{2}(|0\rangle\langle 0| + |1\rangle\langle 1|) \quad (12.14)$$

on  $\mathcal{H}_1$  can be obtained from

$$\frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) \quad (12.15)$$

or from

$$\frac{1}{\sqrt{2}}(|0000\rangle + |1111\rangle) \quad (12.16)$$

or even

$$\frac{1}{\sqrt{2}}(e^{i\phi_1}|00\rangle + e^{i\phi_2}|11\rangle) \quad (12.17)$$

for any real  $\phi_1, \phi_2$  we like.<sup>55</sup>

For mixed states, we can also describe entanglement. Let  $\rho$  be a density operator acting on  $\mathcal{H}_1 \otimes \mathcal{H}_2$ . Such an operator is said to be separable if

$$\rho = \sum_i p_i (\rho_i^{(1)} \otimes \rho_i^{(2)}), \quad \sum p_i = 1, 0 \leq p_i \leq 1. \quad (12.18)$$

If not, it is entangled. Equivalently,  $\rho$  admits a block decomposition

$$\rho = p_1 \begin{pmatrix} \boxed{\rho_1^{(1)}} & \\ & \boxed{\rho_1^{(2)}} \end{pmatrix} + p_2 \begin{pmatrix} \boxed{\rho_2^{(1)}} & \\ & \boxed{\rho_2^{(2)}} \end{pmatrix}. \quad (12.19)$$

Such a state also has entropy, but it is classical (Shannon) entropy from classical correlations.

**Thermal entropy as von Neumann entropy** Let us pick some quantum system with a Hilbert space  $\mathcal{H}$  and Hamiltonian  $\hat{H}$ . For instance, imagine the harmonic oscillator. It has a density operator

$$\hat{\rho}_\beta = \frac{e^{-\beta\hat{H}}}{Z(\beta)}, \quad (12.20)$$

where  $Z$  is the partition function

$$Z(\beta) = \sum_n e^{-\beta E_n}. \quad (12.21)$$

Notice that the partition function (the normalizing factor) is the sum

$$\text{Tr}_{\mathcal{H}}(e^{-\beta\hat{H}}) = \sum_n \langle E_n | e^{-\beta\hat{H}} | E_n \rangle \quad (12.22)$$

$$= \sum_n e^{-\beta E_n}. \quad (12.23)$$

We take  $\beta = 1/k_B T$ . We may write the elements of  $\rho$  in the energy eigenbasis:

$$\rho_\beta = \frac{1}{Z(\beta)} \sum_n e^{-\beta E_n} |E_n\rangle\langle E_n|, \quad (12.24)$$

which has precisely the interpretation of a statistical thermodynamic distribution, with the correct Boltzmann factors  $e^{-\beta E_n}$  weighting each state  $|E_n\rangle\langle E_n|$ . With the partition function, we can therefore compute the free energy

$$F = -k_B T \ln Z(\beta) \quad (12.25)$$

<sup>55</sup>There is a general recipe for purification. For a state  $\rho$  on the Hilbert space  $\mathcal{H}$ , simply take a *maximally entangled state*  $|\Omega\rangle = \sum_i |i\rangle \otimes |i\rangle \in \mathcal{H} \otimes \mathcal{H}$ , where the  $|i\rangle$ s form a complete set of states for  $\mathcal{H}$ . Then write  $|\Psi\rangle = \sqrt{d}(\sqrt{\rho} \otimes \mathbb{I})|\Omega\rangle$ . You can check that such a state is pure by construction and has the right reduced state. Again, see my quantum info notes for the details.

and moreover the entropy

$$S = -\frac{\partial F}{\partial T}, \quad (12.26)$$

from the relation  $dE = TdS + \text{work}$ ,  $F = E - TS \implies dF = -SdT + \text{work}$ .<sup>56</sup> But the (classical) entropy of this distribution is

$$S_{\text{thermal}} = -\sum_n p_n \ln p_n, \quad (12.27)$$

where  $p_n$  is the Boltzmann probability

$$p_n \equiv \frac{e^{-\beta E_n}}{Z(\beta)}. \quad (12.28)$$

And if we compute the von Neumann entropy, we find precisely that

$$S_{\text{vN}} = -\text{Tr}(\rho \ln \rho) = -\sum_n p_n \ln p_n = S_{\text{thermal}}. \quad (12.29)$$

Given  $\hat{\rho}_\beta$  acting on  $\mathcal{H}_i$ , consider

$$|\text{TFD}\rangle \in \mathcal{H} \otimes \mathcal{H} \quad (12.30)$$

the *thermofield double* state. There's a Hamiltonian on  $\mathcal{H} \otimes \mathcal{H}$ , which we can make from the Hamiltonians on the individual  $\mathcal{H}$ s:

$$\hat{H}_{\text{TFD}} = \hat{H} \otimes \mathbb{I} - \mathbb{I} \otimes \hat{H}. \quad (12.31)$$

We may write out the matrix elements

$$|\text{TFD}\rangle = \sum \frac{e^{-\beta E_n/2}}{\sqrt{Z(\beta)}} |E_n\rangle \otimes |E_n\rangle. \quad (12.32)$$

This is a purification of  $\rho_\beta$ <sup>57</sup> and this is a (maximally) entangled pure state in a bipartite system whose function is to reproduce all of thermodynamics in the reduced system.

Lecture 13.

*"The one problem with most physics paradoxes is that when you state them carefully, there's no paradox. Most physics paradoxes are just badly stated."*

–Mukund Rangamani

*Note.* The midterm will cover material up to but not including density matrices, i.e. through chapter 5 of the official course notes. It will go live at 9 AM on Saturday and be due by 9 AM on Sunday on Canvas.

**Entanglement** Entanglement leads to puzzles about locality. Einstein, Podolsky, and Rosen designed a famous thought experiment to test our assumptions about the reality of quantum mechanics. Consider the spin singlet state of two qubits,

$$|\text{EPR}_s\rangle = \frac{1}{\sqrt{2}}(|10\rangle - |01\rangle) \in \mathcal{H}_{\text{qubit}} \otimes \mathcal{H}_{\text{qubit}}. \quad (13.1)$$

This state's total spin is zero. However, the individual qubit spins are anticorrelated. One can prepare such an entangled state locally and then take the second qubit arbitrarily far away (to the moon, or Alpha Centauri).

Because the qubits are anticorrelated, it seems that if we measure e.g. the first qubit, we immediately know something about the second qubit. If we measure  $S_z$  on qubit 1 and get  $+\hbar/2$ , then qubit 2 must have the  $-\hbar/2$  eigenvalue.

Recall that in the projective measurement formalism, for an operator  $A$  we have

$$A|\psi\rangle = \sum_n \alpha_n \langle a_n|\psi\rangle |a_n\rangle. \quad (13.2)$$

Thus when we measure the first spin, we project onto one of the eigenstates. Therefore knowing something about qubit 1 via measurement implies we have gained some knowledge about qubit 2. This seems to be

<sup>56</sup>Work here is usually  $pdV$  in differential form, and the Helmholtz free energy is just a Legendre transformation of the energy.

<sup>57</sup>As I defined above. This is as close as we can get to a canonical purification.

true even if the qubits are spacelike separated, which raises a problem with causality. Access to qubit 2's information should only be possible when causal signals from 2 reach 1.

The problem gets worse when we consider that we could measure any component of spin for qubit 1, i.e. we could choose  $S_x$ ,  $S_y$ , or  $S_z$ . Qubit 2 is anti-correlated, which means any one of these measurements gives information about the corresponding spin component of qubit 2. These operators do not commute, so it seems we have learned too much about the state.

Einstein's proposed resolution was to suggest the existence of local hidden variables. That is, we can construct theories which reproduce some kind of classical probability distribution. However, that statement turns out to be false.

Here's our resolution. The idea that we learned something about qubit 2 by measuring qubit 1 is just too quick. The reason for this is that any measurement on qubit 1 doesn't change  $\rho_2$ , the second subsystem. That is, the reduced state is given by

$$\rho_2 = \text{Tr}_1[|\text{EPR}_s\rangle\langle\text{EPR}_s|] = \frac{1}{2}[|0\rangle\langle 0| + |1\rangle\langle 1|]. \quad (13.3)$$

A measurement of qubit 1 must have the form

$$A_1 \otimes \mathbb{I}|\text{EPR}_s\rangle. \quad (13.4)$$

The problem seems to be therefore with the Copenhagen interpretation suggesting wavefunction collapse. Qubit 2 was really in a mixed state all along— we can see this from the density matrix. Anything we do to qubit 1 therefore doesn't affect qubit 2. That is, if we only know about qubit 2, we cannot predict the outcome of our measurement until the classical information from qubit 1 gets to us. Otherwise, being qubit 1-agnostic, we would have the same 50/50 chance of either outcome.<sup>58</sup>

Quantum teleportation uses entanglement as a resource. For suppose we have an entangled pair of qubits A and B held by Alice and Bob, and Alice moreover has a qubit Q whose state she wants to send to Bob. Alice can therefore make a joint measurement on Q and A and use up the entanglement. She learns something about the joint state of the QA system, at the cost of destroying A. And then she can classically communicate to Bob what she measured on QA, and Bob can perform a basis rotation on B to reconstruct the qubit state A.<sup>59</sup>

**Bell's theorem and local hidden variables** A local hidden variable theory is one in which there exist some classical variables  $\lambda$  with a statistical distribution  $p(\lambda)$  such that

$$\int d\lambda p(\lambda) = 1. \quad (13.5)$$

It was suggested that we could describe quantum mechanics with such a theory. For instance, a spin measurement gives

$$\frac{\hbar}{2}S(\lambda), \quad S(\lambda) = \pm 1. \quad (13.6)$$

More generally, a spin measurement in the direction  $\hat{a} \in \mathbb{R}$  gives

$$\frac{\hbar}{2}S(\hat{a}; \lambda), \quad (13.7)$$

depending both on the hidden classical variable and also on the direction of measurement. The spin operator is

$$S_{\hat{a}} = \sigma \cdot \hat{a}. \quad (13.8)$$

Can we explain correlated measurements in such a theory? Suppose we measure

$$\langle s_{\hat{a}}^1 s_{\hat{b}}^2 \rangle_{\text{LHV}} = - \int d\lambda p(\lambda) S(\hat{a}; \lambda) S(\hat{b}; \lambda). \quad (13.9)$$

<sup>58</sup>Also, there is a property known as monogamy of entanglement. We couldn't actually entangle, say, three qubits in such a way—we can only do it pairwise. This is actually critical for the black hole information paradox.

<sup>59</sup>If you are interested in this, I recommend Ed Witten's notes on quantum information. They are very good and very readable. <https://arxiv.org/abs/1805.11965>

That is, we want to construct such a distribution  $p(\lambda)$  to explain correlation in quantum systems. Let us perform this measurement on the  $|\text{EPR}_s\rangle$  state. If we compute the expected value, we get

$$\langle s_a^1 s_b^2 \rangle_{\text{QM}} = -\cos(\theta_{ab}), \quad \theta_{ab} = \hat{a} \cdot \hat{b}. \quad (13.10)$$

We claim that there exists a  $p(\lambda)$  which reproduces the quantum answer for this correlation. However, John Stuart Bell showed something more powerful. For a set of three measurements,

$$\left| \langle s_a^1 s_b^2 \rangle_{\text{LHV}} - \langle s_a^1 s_c^2 \rangle_{\text{LHV}} \right| \leq 1 + \langle s_a^1 s_c^2 \rangle_{\text{LHV}}. \quad (13.11)$$

This inequality holds in local hidden variable theories. However, it *fails in quantum mechanics*. In the EPR state, if we that  $\hat{a} \cdot \hat{b} = 0$  and  $c = \frac{1}{\sqrt{2}}(\hat{a} + \hat{b})$ , then

$$\left| \langle s_a^1 s_b^2 \rangle_{\text{QM}} - \langle s_a^1 s_c^2 \rangle_{\text{QM}} \right| = \frac{1}{\sqrt{2}}. \quad (13.12)$$

And hence

$$1 + \langle s_a^1 s_c^2 \rangle_{\text{QM}} = 1 - \frac{1}{\sqrt{2}} < \frac{1}{\sqrt{2}}. \quad (13.13)$$

Quantum mechanics violates the Bell inequality, which means that QM is not a LHV theory. Moreover, all you need is one good measurement of a violation of Bell inequalities, and then you can experimentally confirm that our world cannot be described by a local hidden variable theory.<sup>60</sup>

Bell's inequality can be generalized to the CHSH (Clauser-Horne-Shimony-Holt) inequality, which states that

$$\langle s_a^1 s_b^2 \rangle - \langle s_a^1 s_d^2 \rangle + \langle s_c^1 s_b^2 \rangle + \langle s_c^1 s_d^2 \rangle \leq 2 \quad (13.14)$$

in local hidden variables. QM predicts that the LHS is bounded from below by 2 but also bounded from above by  $2\sqrt{2}$ . This upper bound is known as Tsirelson's bound. Previous experimental tests have exceeded 2 with some statistical significance, but no one has yet saturated the upper bound. There are other theories which suggest the upper bound could be violated, but these are still in the minority and we are a little ways off from testing Tsirelson's bound.

Nevertheless, the test of Bell's inequalities are the clearest sign our world is really quantum. Without entanglement, we could not achieve a violation of Bell inequalities. The tensor product structure of quantum mechanics has no classical analog. Everything we know about applications of quantum mechanics rests on this fact, that entanglement is a feature of our fundamentally quantum world.

Lecture 14.

**Tuesday, November 12, 2019**

Midterm scores are back, and basically everyone did great! As it turns out, what we saw in the midterm (two potentially different Hamiltonians with identical spectra apart from the ground state) was a special case of supersymmetric quantum mechanics, a cool topic that we unfortunately won't cover further. That is, the Hamiltonian takes the form  $\mathcal{H} = \{Q, Q^\dagger\}$ , i.e. in terms of some

$$\mathcal{H} = \begin{pmatrix} H & \\ & \tilde{H} \end{pmatrix}, \quad Q = \begin{pmatrix} 0 & 0 \\ A & 0 \end{pmatrix}, \quad Q^\dagger = \begin{pmatrix} 0 & A^\dagger \\ 0 & 0 \end{pmatrix}. \quad (14.1)$$

For instance, the Pöschl-Teller potential we explored as a bonus problem on Homework 5 has a general solution of some hypergeometric functions, but its spectrum reduces to that of the infinite square well for the right values of its parameters.

<sup>60</sup>The Quantum Journal Club speaker, Marina Radulaski, gave a nice talk on this last month. The experimental tests of Bell inequalities are still ongoing but our world really does seem to be quantum.

**Path integral formulation of QM** We now present a thought experiment commonly attributed to Feynman. Suppose we have a double-slit setup, where there is some source, a detector, and a large screen between them. This screen has two slits in it for particles to pass through.

Quantum mechanics tells us that when both slits are open, we must sum the amplitudes for the particle to travel through each of the slits and then to the detector. That is, if the source is at  $p$ , the detector at  $q$ , and the slits at  $h_1, h_2$ , then the total amplitude of finding the particles at  $q$  is

$$\mathcal{A}_{\text{total}} = \mathcal{A}(p \rightarrow h_1 \rightarrow q) + \mathcal{A}(p \rightarrow h_2 \rightarrow q). \quad (14.2)$$

It is clear that if we add a third slit at  $h_3$  we would have to add a term like  $\mathcal{A}(p \rightarrow h_3 \rightarrow q)$ . We could also add more screens. What we realize is that every possible trajectory must be *summed over*. That is, if we label the slits by a superscript representing which screen they are in (e.g. slit 1 in screen 2 is  $h_1^{(2)}$ ), the total amplitude is the sum of all such terms

$$\mathcal{A}_{\text{total}} = \sum_{n,m} \mathcal{A}(p \rightarrow h_n^{(1)} \rightarrow h_m^{(2)} \rightarrow \dots \rightarrow q). \quad (14.3)$$

If we increase the number of screens and the number of slits, we are indeed forced to conclude (in the limit as the number of slits and screens both become infinite) that all possible trajectories through empty space must be summed over, so long as they start at  $p$  at some time  $t_0$  and end at  $q$  at some later fixed time  $t_f$ . That is, they must satisfy the boundary conditions, and the total amplitude is therefore

$$\mathcal{A}_{\text{total}} = \sum_{\text{all paths}} \mathcal{A}_{\text{path}}(p \rightarrow q). \quad (14.4)$$

The problem reduces to finding what the amplitude of an arbitrary path is, and then summing over all such paths.<sup>61</sup>

In fact, we shall argue that this amplitude is given by a (complex) weight related simply to an action:

$$\mathcal{A}_{\text{path}}(p \rightarrow q) = e^{\frac{i}{\hbar} S_{\text{path}}}, \quad (14.5)$$

where

$$S = \int dt L, \quad (14.6)$$

with  $L$  the Lagrangian of a theory. The Lagrangian is generically a function of the coordinates and their derivatives,  $L(x, \dot{x})$ , and the action is a functional of trajectories.

When we compute the equations of motion of the Lagrangian, we get the *classical trajectory* and the corresponding action is called the *on-shell action*. We shall argue that writing QM in this way was in fact inevitable.

The path integral is very elegant, but it is often difficult to compute. There are very few cases where they can be computed exactly. Nevertheless it will be useful to us in some general arguments, and in understanding the structure of quantum mechanics.<sup>62</sup>

**Quantum propagator** Suppose we prepare a particle at some initial position  $p$  at time  $t_0$ , and we would like to know the amplitude of it ending up at some final position  $q$  at some later time  $t$ . In the Schrödinger picture, states (rays in Hilbert space) evolve by unitary time evolution,

$$|\psi(t)\rangle = U(t, t_0) |\psi(t_0)\rangle, \quad (14.7)$$

where for a time-independent Hamiltonian  $\hat{H}$ , we have

$$U = \exp \left[ -\frac{i}{\hbar} \hat{H}(t - t_0) \right]. \quad (14.8)$$

<sup>61</sup>For now, we're restricting ourselves to non-relativistic quantum mechanics, so we take  $c$  to be  $\infty$ . In relativistic QM, something similar can be done but we must be careful about paths that go back in time or otherwise violate causality.

<sup>62</sup>Path integrals are also common in quantum field theory, and ubiquitous in string theory.

If we now project onto the position eigenbasis, we have

$$\langle x|\psi(t)\rangle = \psi(x, t) \quad (14.9)$$

$$= \langle x|\exp\left[-\frac{i}{\hbar}\hat{H}(t-t_0)\right]|\psi(t_0)\rangle. \quad (14.10)$$

Let's try to evaluate this. It would be great to evaluate  $H$  on energy eigenstates, so let us insert two resolutions of the identity  $\sum_n |e_n\rangle\langle e_n|$  and write

$$\begin{aligned} \psi(x, t) &= \sum_{n,m} \langle x|e_n\rangle \langle e_n|e^{-\frac{i}{\hbar}\hat{H}(t-t_0)}|e_m\rangle \langle e_m|\psi(t_0)\rangle \\ &= \sum_n \langle x|e_n\rangle \langle e_n|\psi(t_0)\rangle e^{-\frac{i}{\hbar}E_n(t-t_0)} \\ &= \sum_n \phi_n(x) c_n(t_0) e^{-\frac{i}{\hbar}E_n(t-t_0)}, \end{aligned} \quad (14.11)$$

where we have defined the position space wavefunctions  $\phi_n(x)$  of the energy eigenstates  $|e_n\rangle$  and the projections  $c_n$  of  $|\psi(t_0)\rangle$  onto the energy eigenbasis:

$$\langle x|e_n\rangle = \phi_n(x), \quad \langle e_n|\psi(t_0)\rangle = c_n(t_0). \quad (14.12)$$

Working in the energy eigenbasis is great because all time dependence becomes complex phases. We could also expand out these components  $c_n(t_0)$  as an integral in the position eigenbasis, i.e.

$$c_n(t_0) = \int_{-\infty}^{\infty} dx \langle e_n|x\rangle \langle x|\psi(t_0)\rangle \quad (14.13)$$

$$= \int_{-\infty}^{\infty} dx \phi_n^*(x) \psi(x, t_0). \quad (14.14)$$

Finally, we can use this to rewrite the time-dependent position space wavefunction as

$$\begin{aligned} \psi(x, t) &= \int_{-\infty}^{\infty} dx' \left[ \sum_n \phi_n^*(x') \phi_n(x) e^{-\frac{i}{\hbar}E_n(t-t_0)} \right] \psi(x', t_0) \\ &= \int_{-\infty}^{\infty} dx' K(x, t; x', t_0) \psi(x', t_0). \end{aligned} \quad (14.15)$$

That is, the wavefunction at later times is an integral transform of the original wavefunction at time  $t_0$ , where we have defined a quantity  $K(x, t; x', t_0)$ . We know this gadget. It is a *Green's function*.

We call this the *quantum propagator*. It is the Green's function for the time-dependent Schrödinger operator.<sup>63</sup> That is,

$$\left[ \frac{\hat{p}^2}{2m} + V(\hat{x}) - \frac{i}{\hbar} \frac{\partial}{\partial t} \right] K(x, t; x', t') = -i\hbar \delta(x - x') \delta(t - t'). \quad (14.16)$$

**Properties of the propagator** There are some useful alternate ways of writing the propagator. For instance,

$$K(x, t; x', t') = \sum_n \phi_n^*(x') \phi_n(x) e^{-\frac{i}{\hbar}E_n(t-t')}. \quad (14.17)$$

This is nice when we know the wavefunctions  $\phi_n(x)$  of the energy eigenbasis, as in the harmonic oscillator with the Hermite polynomials. But by reversing some of our manipulations, we can also turn this into an inner product over a pair of position eigenstates,

$$K(x, t; x', t') = \langle x|e^{-\frac{i}{\hbar}\hat{H}(t-t')}|x'\rangle \quad (14.18)$$

$$= \langle x|e^{-\frac{i}{\hbar}\hat{H}t} e^{\frac{i}{\hbar}\hat{H}t'}|x'\rangle = \langle x, t|x', t'\rangle. \quad (14.19)$$

We recognize that the propagator is exactly the transition amplitude we were looking for; it measures the overlap between position eigenstates  $x', x$  as evaluated at times  $t'$  and  $t$ .

<sup>63</sup>There is a lovely analogy to QFT here. The propagator that appears in Feynman diagrams is precisely the Green's function for the equations of motion of the field, e.g. Klein-Gordon or Dirac.

For the free particle ( $\hat{H}_{\text{free}} = \frac{\hat{p}^2}{2m}$ ), we can compute the propagator explicitly:

$$K(x, t; x', t') = \langle x | e^{-\frac{i}{\hbar} \hat{H}_{\text{free}}(t-t')} | x' \rangle \quad (14.20)$$

$$= \int_{-\infty}^{\infty} dp dp' \langle x | p \rangle \langle p | e^{-\frac{i}{\hbar} \frac{p^2}{2m}(t-t')} | p' \rangle \langle p' | x' \rangle \quad (14.21)$$

$$= \int_{-\infty}^{\infty} \frac{dp}{(2\pi\hbar)} e^{\frac{i}{\hbar}(x-x')p} e^{-\frac{i}{\hbar} \frac{p^2}{2m}(t-t')}, \quad (14.22)$$

where we have replaced  $\hat{p}$  by its eigenvalue  $p$  and performed one of the  $p$  integrals with the delta function from  $\langle p | p' \rangle$ . Hence we get

$$K(x, t; x', t') = \int_{-\infty}^{\infty} \frac{dp}{(2\pi\hbar)} e^{\frac{i}{\hbar}(x-x')p} e^{-\frac{i}{\hbar} \frac{p^2}{2m}(t-t')} \quad (14.23)$$

$$= \sqrt{\frac{m}{2\pi i \hbar (t-t')}} e^{\frac{im}{2\hbar} \frac{(x-x')^2}{t-t'}}. \quad (14.24)$$

We've performed a Gaussian integral to evaluate the  $dp$  integral.<sup>64</sup>

As a fun aside, if we remove the  $i$  from the  $\frac{\partial}{\partial t}$ , our Schrödinger equation just reduces to the heat equation. That is, our expression (up to factors of  $i$ ) is the heat kernel, the propagator for the heat equation describing heat flow in continuum mechanics. The heat equation is famously non-causal; it treats time differently than space (one time derivative, two in space) and so we see that propagators over very short times  $t \rightarrow t'$  may have very large amplitudes, even if the distances are large. The speed of light never factors into our calculation.

**Sum over paths** There is one more form of the propagator we must know. It is

$$K(x_f, t_f; x_i, t_i) = \int [\mathcal{D}x] e^{\frac{iS}{\hbar}} \quad (14.25)$$

with boundary conditions  $x(t_i) = x_i, x(t_f) = x_f$ , where  $\int [\mathcal{D}x] = \sum_{\text{paths}}$  is simply a bit of notation we've introduced.

Well, what is the total transition amplitude? To find it, we must discretize time. That is, break up the interval  $[t_i, t_f]$  into finite time steps  $\delta t$ . Notice that we can rewrite our propagator as

$$K(x_f, t_f; x_i, t_i) = \langle x_f, t_f | x_i, t_i \rangle = \int dx \langle x_f, t_f | x, t \rangle \langle x, t | x_i, t_i \rangle, \quad (14.26)$$

where we've just inserted a complete set of states  $\int dx |x, t\rangle \langle x, t|$  at some intermediate time  $t \in [t_i, t_f]$ . In particular, we'll split the interval into  $N+1$  segments of size  $\delta t = (t_f - t_i)/(N+1)$  such that

$$t_n = t_1 + n\delta t \quad (14.27)$$

$$t_f = t_{N+1} = t_i + (N+1)\delta t. \quad (14.28)$$

It is clear that

$$t_i < t_1 < t_2 \dots < t_N < t_f. \quad (14.29)$$

By inserting a complete set of states at every step, we see that

$$\langle x_f, t_f | x_i, t_i \rangle = \int dx_N \dots \int dx_1 \langle x_f, t_f | x_N, t_N \rangle \langle x_N, t_N | x_{N-1}, t_{N-1} \rangle, \dots \langle x_1, t_1 | x_i, t_i \rangle. \quad (14.30)$$

We can then take the limit as  $N \rightarrow \infty$  and  $\delta t \rightarrow dt$  becomes infinitesimally small. To evaluate this expression, consider a single one of these inner products  $\langle x_n, t_n | x_{n-1}, t_{n-1} \rangle$ . It is

$$\langle x_n, t_n | x_{n-1}, t_{n-1} \rangle = \langle x_n | e^{-\frac{i}{\hbar} \hat{H}(t_n - t_{n-1})} | x_{n-1} \rangle \quad (14.31)$$

$$= \langle x_n | e^{-\frac{i}{\hbar} \delta t \hat{H}} | x_{n-1} \rangle \quad (14.32)$$

<sup>64</sup>Strictly, we need to use analytic continuation and an  $i\epsilon$  prescription. That is, if we're being careful, we perform this as an integral in the complex plane so that it will actually converge.

What's difficult about evaluating the Hamiltonian on position eigenstates is that in general, we cannot split up the exponential:

$$e^{-\frac{i}{\hbar}\delta t \hat{H}} = e^{-\frac{i}{\hbar}\delta t (\frac{\hat{p}^2}{2m} + V(\hat{x}))} \neq e^{-\frac{i}{\hbar}\delta t \frac{\hat{p}^2}{2m}} \cdot e^{-\frac{i}{\hbar}\delta t V(\hat{x})}. \quad (14.33)$$

However, if  $\delta t \ll 1$ , then

$$e^{-\frac{i}{\hbar}\delta t (\frac{\hat{p}^2}{2m} + V(\hat{x}))} = e^{-\frac{i}{\hbar}\delta t \frac{\hat{p}^2}{2m}} \cdot e^{-\frac{i}{\hbar}\delta t V(\hat{x})} + O(\delta t^2). \quad (14.34)$$

That is, the errors have to do with the commutator of  $\hat{p}^2$  and  $V(\hat{x})$ ,<sup>65</sup> and they are higher-order in  $\delta t$ , so we can safely neglect them as  $\delta t \rightarrow 0$ . Thus to order  $\delta t$ ,

$$\langle x_n, t_n | x_{n-1}, t_{n-1} \rangle = \langle x_n | e^{-\frac{i}{\hbar}\delta t \frac{\hat{p}^2}{2m}} \cdot e^{-\frac{i}{\hbar}\delta t V(\hat{x})} | x_{n-1} \rangle + O(\delta t^2) \quad (14.35)$$

$$= \int dp \langle x_n | e^{-i\frac{\hat{p}^2}{2m}\delta t} | p \rangle \langle p | x_{n-1} \rangle e^{-\frac{i}{\hbar}V(x_{n-1})\delta t} \quad (14.36)$$

$$= \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} dp \exp\left(-\frac{i}{2m\hbar}p^2\delta t + \frac{i}{\hbar}p(x_n - x_{n-1})\right) \times \exp\left(-\frac{i}{\hbar}V(x_{n-1})\delta t\right) \quad (14.37)$$

$$= \sqrt{\frac{m}{2\pi\hbar\delta t}} \exp\left(\frac{im}{2\hbar} \left[\frac{(x_n - x_{n-1})^2}{\delta t}\right] - \frac{iV(x_{n-1})\delta t}{\hbar}\right). \quad (14.38)$$

We have inserted a complete set of states and performed the Gaussian integrals, as before. Hence we can now put this back into our expression for the overall propagator. That is,

$$\langle x_f, t_f | x_i, t_i \rangle = \int dx_N \dots \int dx_1 \left(\frac{m}{2\pi\hbar i\delta t}\right)^{\frac{N+1}{2}} \exp\left[\frac{i\delta t}{\hbar} \left(\sum_{n=0}^N \frac{m}{2} \frac{(x_n - x_{n-1})^2}{\delta t^2} - V(x_{n-1})\right)\right] \quad (14.39)$$

$$= \int [\mathcal{D}x] \exp\left(\frac{i}{\hbar} \int_{t_i}^{t_f} dt \left[\frac{m}{2} \left(\frac{dx}{dt}\right)^2 - V(x)\right]\right), \quad (14.40)$$

and we see that when we discretized time, our manipulations exactly performed the Legendre transform to take us from the Hamiltonian to the Lagrangian.

Lecture 15.

**Thursday, November 14, 2019**

Previously, we introduced the path integral and the quantum propagator. We said that

$$\langle x_f, t_f | x_i, t_i \rangle \equiv K(x_f, t_f; x_i, t_i) \quad (15.1)$$

$$= \int [\mathcal{D}x(t)] e^{iS[x(t)]/\hbar} \quad (15.2)$$

$$= \sum_{\text{paths}} e^{iS/\hbar}. \quad (15.3)$$

That is, the quantum propagator measures the amplitude of propagation from a position eigenstate  $x_i$  at time  $t_i$  to another position eigenstate  $x_f$  at time  $t_f$ . The integration measure was the continuous limit of a discretized set of small steps  $dx_i$ :

$$\int [\mathcal{D}x(t)] = \int dx_N \dots \int dx_1 \left(\frac{m}{2\pi\hbar i\delta t}\right)^{\frac{N+1}{2}}. \quad (15.4)$$

**Free particle path integral** Let's compute this exactly for the free particle,. That is, we set  $V(x) = 0$  so that

$$S[x] = \int_{t_i}^{t_f} dt \frac{1}{2} m \dot{x}^2. \quad (15.5)$$

Let us also denote the normalization factor from the Gaussian integral as

$$\mathcal{N}_1 \equiv \left(\frac{m}{2\pi\hbar i\delta t}\right)^{1/2} \quad (15.6)$$

<sup>65</sup>More precisely, we can work them out with the BCH formula mentioned earlier.

so that the path integral now takes the form

$$\langle x_f, t_f | x_i, t_i \rangle = \int [\mathcal{D}x(t)] e^{iS[x(t)]/\hbar} \quad (15.7)$$

$$= \lim_{N \rightarrow \infty, \delta t \rightarrow 0} \int dx_N \dots \int dx_1 \mathcal{N}_1^{N+1} \exp \left[ \frac{i}{\hbar} \sum_{n=1}^N \frac{(x_n - x_{n-1})^2}{(\delta t)^2} \delta t \frac{m}{2} \right] \quad (15.8)$$

$$+ \frac{i}{\hbar} \frac{m}{2} \frac{(x_1 - x_i)^2}{\delta t} + \frac{i}{\hbar} \frac{m}{2} \frac{(x_f - x_N)^2}{\delta t} \Big]. \quad (15.9)$$

These are simply a bunch of Gaussian integrals (up to analytic continuation), so in principle we can just compute them exactly. Define

$$\xi_n = \frac{m}{2\hbar\delta t} x_n. \quad (15.10)$$

Then our propagator can be written as

$$\begin{aligned} \langle x_f, t_f | x_i, t_i \rangle &= \lim_{N \rightarrow \infty, \delta t \rightarrow 0} \mathcal{N}_1^{N+1} \left( \frac{2\hbar\delta t}{m} \right)^{N/2} \int d\xi_N \dots \int d\xi_1 \\ &\quad \times \exp \left[ i(\xi_1 - \xi_i)^2 + i(\xi_f - \xi_N)^2 + i \sum_{n=1}^N (\xi_{n+1} - \xi_n)^2 \right]. \end{aligned} \quad (15.11)$$

Performing the  $\xi_1$  integral gives

$$\int d\xi_1 e^{-\frac{1}{i}(\xi_1 - \xi_i)^2 - \frac{1}{i}(\xi_2 - \xi_1)^2} = \sqrt{\frac{\pi i}{2}} e^{-\frac{1}{2i}(\xi_2 - \xi_i)^2}. \quad (15.12)$$

We see that performing the  $\xi_1$  integral gives us a factor for the  $\xi_2$  integral. That is, the next integral is<sup>66</sup>

$$\int d\xi_2 e^{-\frac{1}{i}(\xi_3 - \xi_2)^2 - \frac{1}{2i}(\xi_2 - \xi_i)^2} = \sqrt{\frac{2\pi i}{3}} e^{-\frac{1}{3i}(\xi_3 - \xi_i)^2}. \quad (15.13)$$

This pattern holds up. For  $N$  such integrals,

$$\langle x_f, t_f | x_i, t_i \rangle = \lim_{N \rightarrow \infty, \delta t \rightarrow 0} \mathcal{N}_1^{N+1} \left( \frac{2\hbar\delta t}{m} \right)^{N/2} \left( \prod_{k=1}^N \sqrt{\frac{\pi k i}{k+1}} \right) \exp \left[ -\frac{1}{(N+1)i} (\xi_f - \xi_i)^2 \right] \quad (15.14)$$

$$= \lim_{N \rightarrow \infty, \delta t \rightarrow 0} \sqrt{\frac{m}{2\pi i \hbar (N+1) \delta t}} \exp \left[ \frac{im}{2\pi \hbar (N+1) \delta t} (x_f - x_i)^2 \right]. \quad (15.15)$$

We now see that the limit is well-defined, since we always get the factor  $(N+1)\delta t$ , which is simply the time interval between the start and end points,  $(N+1)\delta t = t_f - t_i = \Delta t$ . We conclude that

$$\langle x_f, t_f | x_i, t_i \rangle = \sqrt{\frac{m}{2\pi i \hbar (t_f - t_i)}} \exp \left[ \frac{im(x_f - x_i)^2}{2\hbar(t_f - t_i)} \right]. \quad (15.16)$$

This is the same propagator we found by going to Fourier space in the previous lecture, as Eqn. 14.24.

One point that might concern us— we never used the canonical commutation relations in the derivation of the path integral. We shall see later that the path integral will still give us some equivalent of commutation relations consistent with canonical quantization.

There's also a much quicker way to do this computation. We use the expression

$$\int \prod_{n=1}^N dx_n \exp \left( -\frac{1}{2} \mathbf{z}^T \cdot \mathbf{M} \cdot \mathbf{z} - \mathbf{z}^T \cdot \mathbf{x} \right) = (2\pi)^{N/2} \frac{1}{\sqrt{\det \mathbf{M}}} e^{\frac{1}{2} \mathbf{x}^T \cdot \mathbf{M}^{-1} \cdot \mathbf{x}}. \quad (15.17)$$

Here,  $\mathbf{z}$  is a vector

$$\mathbf{z} = \begin{pmatrix} z_1 \\ \vdots \\ z_n \end{pmatrix} \quad (15.18)$$

<sup>66</sup>Exercise to check this.

and  $\mathbf{x}$  is similarly some shift vector. The exponent can equivalently be written as

$$-\frac{1}{2} \sum_{i,j=1}^N z_i z_j M_{ij} - \sum_{i=1}^N z_i x_i. \quad (15.19)$$

This formula can be proven by induction or alternately by diagonalizing the matrix  $M$ . In our case,

$$\mathbf{z} = \begin{pmatrix} z_1 \\ \vdots \\ z_n \end{pmatrix}, \quad M = \frac{2}{i} \begin{pmatrix} 1 & -\frac{1}{2} & 0 & \dots & 0 & 0 \\ -\frac{1}{2} & 1 & -\frac{1}{2} & \dots & & \vdots \\ \vdots & & & & & \\ \vdots & & & & 1 & -\frac{1}{2} \\ 0 & 0 & 0 & -\frac{1}{2} & 1 \end{pmatrix}, \quad \mathbf{x} = -\frac{2}{i} \begin{pmatrix} \xi_i \\ 0 \\ \vdots \\ 0 \\ \xi_f \end{pmatrix}. \quad (15.20)$$

Plugging in values and taking the determinant of  $M$  yields our free particle propagator.

**Harmonic oscillator** Let us now turn our attention to the harmonic oscillator. Let's do this path integral in a different way. Let us write paths in terms of their deviations from the classical path, as

$$x(t) = x_{\text{cl}}(t) + \delta x(t). \quad (15.21)$$

What we must integrate over is now the deviations  $\delta x(t)$ . We also recall that the integrand is a functional of the path,  $S[x(t)]$ .

The Lagrangian is

$$\mathcal{L} = \frac{1}{2} m \dot{x}^2 - \frac{1}{2} m \omega^2 x^2, \quad (15.22)$$

and our boundary conditions are

$$x(t_i) = x_i, \quad x(t_f) = x_f. \quad (15.23)$$

Computing the Euler-Lagrange equations for this Lagrangian gives us our well-known solutions of sines and cosines; fitting the boundary conditions then yields

$$x_{\text{cl}}(t) = x_i \frac{\sin \omega(t_f - t)}{\sin \omega(t_f - t_i)} + x_f \frac{\sin \omega(t - t_i)}{\sin \omega(t_f - t_i)}. \quad (15.24)$$

Let us evaluate the on-shell action, i.e.  $S[x_{\text{cl}}(t)]$ . That is,

$$S_{\text{on-shell}} = \int_{t_i}^{t_f} dt \left[ \frac{1}{2} m \dot{x}_{\text{cl}}^2 - \frac{1}{2} m \omega^2 x_{\text{cl}}^2 \right]. \quad (15.25)$$

There is an easy way and a hard way to compute this. The hard way is to just plug in  $x_{\text{cl}}(t)$ , which we can do if we like computing horrible integrals. The easy way is to recognize that  $x_{\text{cl}}$  satisfies the equations of motion by definition, so we can integrate the kinetic term of the on-shell action by parts as

$$S_{\text{on-shell}} = \int_{t_i}^{t_f} -\frac{m}{2} (x_{\text{cl}} \ddot{x}_{\text{cl}} + \omega^2 x_{\text{cl}}^2) dt + \int_{t_i}^{t_f} dt \frac{d}{dt} \left[ \frac{m}{2} x_{\text{cl}} \dot{x}_{\text{cl}} \right]. \quad (15.26)$$

The first term is now proportional to the equations of motion, so it vanishes. What remains is the boundary term,

$$S_{\text{on-shell}} = \frac{m}{2} x_{\text{cl}} \frac{dx_{\text{cl}}}{dt} \Big|_{t_i}^{t_f} = \frac{1}{2} m \omega \frac{(x_i^2 + x_f^2) \cos \omega(t_f - t_i) - 2x_i x_f}{\sin \omega(t_f - t_i)}. \quad (15.27)$$

This principle holds more generally; the on-shell action is always a boundary term because we can always integrate by parts.<sup>67</sup>

Now we can expand a general path in terms of its deviation from the classical path. That is, if

$$x(t) = x_{\text{cl}}(t) + \delta x(t), \quad (15.28)$$

<sup>67</sup>That is, so long as the kinetic term is quadratic in the velocity  $\dot{x}$ , this trick works. The factor of  $x$  after integrating by parts compensates for the derivative with respect to  $x$  in the Euler-Lagrange equations.

then the action on such a path is

$$\int dt \mathcal{L}[x_{\text{cl}}(t) + \delta x(t)] = \int dt \left\{ \mathcal{L}[x_{\text{cl}}(t)] + \frac{\delta \mathcal{L}}{\delta x(t)} \Big|_{x=x_{\text{cl}}(t)} \delta x(t) + \frac{1}{2} \frac{\delta^2 \mathcal{L}}{(\delta x(t))^2} \Big|_{x=x_{\text{cl}}(t)} (\delta x(t))^2 + \dots \right\}. \quad (15.29)$$

This second term is in fact zero. That's just the condition that the first-order variation of the Lagrangian about the classical path vanishes because the classical path satisfies the equations of motion.

In general there are higher-order corrections, but for the harmonic oscillator, the series in fact terminates here. There are no  $(\delta x(t))^3$  or higher order terms.

We are also free to parametrize the deviation  $\delta x(t)$  however we like. In particular, let us expand it as a Fourier series, since it vanishes at  $t_i$  and  $t_f$ . That is,

$$\delta x(t) = \sum_{n=0}^{\infty} \zeta_n \sin\left(\frac{n\pi(t-t_i)}{t_f-t_i}\right), \quad (15.30)$$

which by construction fits the boundary conditions

$$\delta x(t_i) = \delta x(t_f) = 0. \quad (15.31)$$

Now it's a bit of a computation to show that

$$S[x_{\text{cl}}(t) + \delta x(t)] = S_{\text{on-shell}} + \frac{m}{4} \sum_{n=0}^{\infty} \left( \frac{n^2 \pi^2}{t_f - t_i} - \omega^2(t_f - t_i) \right) \zeta_n^2. \quad (15.32)$$

The first term is just the on-shell action; the second comes from the fact we have the  $dt$  integral, and the Fourier modes are orthogonal. Hence after performing the  $dt$  integral we only get terms proportional to  $\zeta_n^2$ , the diagonal elements. The only thing to compute is the normalization.<sup>68</sup>

So much for the action. What about the integration measure? It is

$$[\mathcal{D}x] = \sqrt{\frac{m}{2\pi i \hbar (t_f - t_i)}} \prod_{n=1}^{\infty} \sqrt{\frac{m}{2\pi i \hbar (t_f - t_i)}} \frac{n\pi}{\sqrt{2}} d\zeta_n. \quad (15.33)$$

We haven't shown this formally, but it follows from a change of variables (e.g. the  $n\pi$  comes from the Fourier modes).

If we put it all together, we find that

$$\begin{aligned} \langle x_f, t_f | x_i, t_i \rangle &= e^{i S_{\text{on-shell}}} \sqrt{\frac{m}{2\pi i \hbar (t_f - t_i)}} \left[ \prod_{n=1}^{\infty} \sqrt{\frac{m}{2\pi i \hbar (t_f - t_i)}} \frac{n\pi}{\sqrt{2}} \right. \\ &\quad \left. \times \int d\zeta_n \exp\left(\frac{im}{4\hbar} \left\{ \frac{n^2 \pi^2}{t_f - t_i} - \omega^2(t_f - t_i) \right\} \zeta_n^2 \right) \right] \end{aligned} \quad (15.34)$$

If we do these (infinitely many) Gaussian integrals, we get

$$\langle x_f, t_f | x_i, t_i \rangle = e^{i S_{\text{on-shell}}} \sqrt{\frac{m}{2\pi i \hbar (t_f - t_i)}} \prod_{n=1}^{\infty} \left( 1 - \frac{\omega^2(t_f - t_i)^2}{n^2 \pi^2} \right)^{-1/2} \quad (15.35)$$

$$= e^{i S_{\text{on-shell}}} \sqrt{\frac{m\omega}{2\pi i \hbar \sin \omega(t_f - t_i)}}. \quad (15.36)$$

We used an infinite product formula

$$\frac{\sin \pi z}{z} = \prod_{n=1}^{\infty} \left( 1 - \frac{z^2}{n^2} \right). \quad (15.37)$$

We can understand this formula intuitively—notice that  $\sin \pi z / z$  has roots at all the integers. The right side is a product of terms which give us precisely these roots.<sup>69</sup> Moreover, notice that as  $\omega \rightarrow 0$ , we get back the free-particle propagator.

<sup>68</sup>Exercise to check this.

<sup>69</sup>This is an example of the Weierstrass factorization theorem, see for example [https://en.wikipedia.org/wiki/Weierstrass\\_factorization\\_theorem](https://en.wikipedia.org/wiki/Weierstrass_factorization_theorem).

Suppose now we take  $t_f - t_i = i\beta$ . The sine becomes a hyperbolic sine, and we in fact recover the partition function of the harmonic oscillator,

$$\sum_{n=0}^{\infty} e^{-\hbar(n+\frac{1}{2})\beta\omega} = \frac{1}{2 \sin \frac{\beta\omega\hbar}{2}}. \quad (15.38)$$

Hence quantum mechanics, analytically continued to imaginary time, reduces to statistical mechanics.

Lecture 16.

**Tuesday, November 19, 2019**

**Path integrals and canonical quantization** Today we'll examine the connection between path integrals and canonical quantization. Let us recall that

$$\langle x_f, t_f | x_i, t_i \rangle = \int [\mathcal{D}x(t)] e^{\frac{i}{\hbar} S[x(t)]}. \quad (16.1)$$

We can now make a change of variables, i.e. consider a reparametrization

$$x(t) \rightarrow x(t) + \delta x(t), \quad \delta x(t_i) = \delta x(t_f) = 0. \quad (16.2)$$

That is, we consider a variation in the path. Hence

$$S[x(t)] \rightarrow S[x(t) + \delta x(t)] = S[x(t)] + \frac{\delta S}{\delta x} \delta x(t) + \dots, \quad (16.3)$$

and we now consider the quantity

$$\int [\mathcal{D}(x(t) + \delta x(t))] e^{\frac{i}{\hbar} S[x(t) + \delta x(t)]} - \int [\mathcal{D}x(t)] e^{\frac{i}{\hbar} S[x(t)]}. \quad (16.4)$$

That is, how much has the path integral changed under this variation? Since  $x(t) \rightarrow x(t) + \delta x(t)$  is just relabeling paths and  $\mathcal{D}$  tells us to sum over all paths, we have

$$[\mathcal{D}(x(t) + \delta x(t))] = [\mathcal{D}x(t)]. \quad (16.5)$$

Hence our expression is

$$\int [\mathcal{D}x(t)] \left\{ e^{\frac{i}{\hbar} (S[x(t)] + \frac{\delta S}{\delta x} \delta x)} - e^{\frac{i}{\hbar} S[x(t)]} \right\}, \quad (16.6)$$

and keeping terms to  $O(\delta x)$  we find that

$$\int [\mathcal{D}x(t)] e^{\frac{i}{\hbar} S[x(t)]} \left( 1 + \frac{i\delta S}{\hbar \delta x} \delta x - 1 \right) = \frac{i}{\hbar} \int [\mathcal{D}x(t)] e^{\frac{i}{\hbar} S[x(t)]} \frac{\delta S}{\delta x} \delta x. \quad (16.7)$$

Hence the fact that relabeling paths (with fixed boundary conditions) doesn't change  $\langle x_f, t_f | x_i, t_i \rangle$  tells us that

$$\int [\mathcal{D}x(t)] e^{\frac{iS}{\hbar}} \frac{\delta S}{\delta x} \delta x = 0. \quad (16.8)$$

We use the fact that

$$\frac{\delta S}{\delta x} \delta x = \delta_{\text{tot}} S, \quad (16.9)$$

which tells us that

$$\langle \delta_{\text{tot}} S \rangle = 0, \quad (16.10)$$

where we define expectation values to be

$$\langle A \rangle = \frac{\int [\mathcal{D}x(t)] A e^{\frac{i}{\hbar} S[x(t)]}}{\int [\mathcal{D}x(t)] e^{\frac{i}{\hbar} S[x(t)]}}. \quad (16.11)$$

For instance, in the harmonic oscillator we would have

$$\langle \hat{x}^2(\tilde{t}) \rangle = \frac{\int [\mathcal{D}x(t)] x(\tilde{t})^2 e^{\frac{iS[x(t)]}{\hbar}}}{\int [\mathcal{D}x(t)] e^{\frac{iS[x(t)]}{\hbar}}}. \quad (16.12)$$

But if  $\delta_{\text{tot}}S$  vanishes, then we recover the classical equations of motion. This tells us that *classical equations of motion hold inside expectation values*. This is Ehrenfest's theorem.<sup>70</sup>  $S[\hat{x}, \hat{p}]$  is an operator, as is  $\delta_{\text{tot}}S$ . Quantum mechanics realizes the classical equations of motion as an expectation value/average statement

$$\langle \delta_{\text{tot}}S \rangle = 0. \quad (16.13)$$

We have spent a whole lecture trying to calculate the denominator that appears in the path integral expectation value. But in general this same factor appears both in the numerator and denominator, so the exact normalization of the path integral is not usually too important. The one place it does matter is when we Wick rotate (analytically continue) to imaginary time— then the integral has the interpretation of the thermal partition function  $Z$ , as we saw on homework 6.<sup>71</sup>

**Canonical quantization** We would like to show that the momentum operator actually has the form  $\hat{p} = -i\hbar \frac{\partial}{\partial x}$  in the position basis. Rather than varying the entire path, let us move one of the endpoints. That is, we consider the difference

$$\langle x_f + \delta x_f, t_f | x_i, t_i \rangle - \langle x_f, t_f | x_i, t_i \rangle, \quad (16.14)$$

keeping the time interval  $[t_i, t_f]$  fixed. Taylor expanding the first term, this difference is therefore

$$\frac{\partial}{\partial x_f} \langle x_f, t_f | x_i, t_i \rangle \delta x_f \quad (16.15)$$

to linear order in  $\delta x_f$ . Then

$$\frac{\partial}{\partial x_f} \langle x_f, t_f | x_i, t_i \rangle \delta x_f = \int [\mathcal{D}x(t)] e^{iS[x(t) + \delta x(t)/\hbar]} - \int [\mathcal{D}x(t)] e^{iS[x(t)]} \quad (16.16)$$

$$= \int [\mathcal{D}x(t)] \left( \frac{i}{\hbar} \delta_{\text{tot}}S \right) e^{iS[x(t)]} \quad (16.17)$$

$$= \int [\mathcal{D}x(t)] \frac{i}{\hbar} \left[ \int_{t_i}^{t_f} \left( \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}} \right) - \frac{\partial \mathcal{L}}{\partial x} \right) dt + \frac{\partial \mathcal{L}}{\partial \dot{x}} \delta x \Big|_{x_i}^{x_f} \right] e^{iS}. \quad (16.18)$$

That is, we rewrote the path integrals from the previous equation in integral form, and we found that what appears is again the total variation of the action. Note that the integration measure  $[\mathcal{D}x(t)]$  doesn't change even when we change the endpoints.<sup>72</sup>

But now this first term is zero because the trajectories satisfy the equations of motion upon taking the expectation value. What remains is a non-vanishing boundary term;  $\delta x$  is  $\delta x_f$  at  $x_f$ , so we find that the RHS reduces to

$$\int [\mathcal{D}x(t)] e^{iS} \frac{i}{\hbar} \frac{\partial \mathcal{L}}{\partial \dot{x}} \Big|_{x_f} \delta x_f = \int [\mathcal{D}x(t)] e^{iS} \frac{i}{\hbar} p_f \delta x_f. \quad (16.19)$$

By comparing to the derivative expression, we conclude that

$$\frac{\partial}{\partial x_f} \langle x_f, t_f | x_i, t_i \rangle = \int [\mathcal{D}x(t)] e^{iS} \frac{i}{\hbar} p_f \implies p_f = -i\hbar \frac{\partial}{\partial x_f} \quad (16.20)$$

The reason this worked is because we've secretly been using the Heisenberg equations of motion, i.e. that time evolution happens by  $U(t) = e^{-iHt/\hbar}$ .

Similarly one can check<sup>73</sup> that

$$\frac{\partial}{\partial t_f} \langle x_f, t_f | x_i, t_i \rangle = \int [\mathcal{D}x(t)] e^{iS} \frac{i}{\hbar} (-H(t_f)). \quad (16.21)$$

Hence we recover Schrödinger's equation from the path integral. Indeed, we can derive the representation of all sorts of conserved quantities by considering variations of path integrals, e.g. the angular momentum operator from rotational invariance. Such average operator-level identities are known as Ward identities.

<sup>70</sup>This is not the same as saying that expectation values obey classical equations of motion! Clearly,  $\langle x \rangle^2$  and  $\langle x^2 \rangle$  are in general different quantities. When we apply the theorem, it's the latter we want to use.

<sup>71</sup>In QFT, we sometimes denote this factor by  $Z$  anyway to emphasize the analogy.

<sup>72</sup>This is like going from the interval  $[a, b]$  to  $[a, b + \delta b]$ . The measure  $dx$  doesn't change.

<sup>73</sup>Exercise.

**Connection to statistical mechanics** Recall that the thermal partition function is

$$Z(\beta) = \sum_n e^{-\beta E_n} \quad (16.22)$$

$$= \int_{-\infty}^{\infty} dx K(x, -i\beta\hbar; x, 0), \quad (16.23)$$

as we proved on the homework. That is, we rotate to Euclidean time.<sup>74</sup> We define  $t_E = it$ , where  $t$  was the physical time (in Lorentzian signature, if we like). Hence  $dt = -idt_E$ , so that

$$S = \int dt \left[ \frac{m}{2} \left( \frac{dx}{dt} \right)^2 - V(x) \right] \rightarrow i \int dt_E \left[ \frac{m}{2} \left( \frac{dx}{dt_E} \right)^2 + V(x) \right] \equiv iS_E[x], \quad (16.24)$$

This rewritten term now looks like a Hamiltonian, but with respect to Euclidean time rather than physical time. The quantity  $S_E$  denotes the *Euclidean action*.<sup>75</sup> Hence

$$\int [\mathcal{D}x] e^{\frac{i}{\hbar} \int dt \left[ \frac{m}{2} \left( \frac{dx}{dt} \right)^2 - V(x) \right]} \xrightarrow{t \rightarrow -it_E} \int [\mathcal{D}x] e^{-\frac{1}{\hbar} S_E[x]}. \quad (16.25)$$

If our Hamiltonian is to be sensible (stable), then its value must be bounded from below, which means that instead of some oscillating function we now have something that converges nicely; it is exponentially damped.

For our last trick, let's show that if we evaluate this for the harmonic oscillator, we get the harmonic oscillator partition function. In real time we had the path integral

$$K(x_f, t_f; x_i, t_i) = \exp \left[ \frac{im\omega}{\hbar} \frac{(x_i^2 + x_f^2) \cos \omega(t_f - t_i) - 2x_i x_f}{\sin \omega(t_f - t_i)} \right] \sqrt{\frac{m\omega}{2\pi i \hbar \sin(\omega(t_f - t_i))}}. \quad (16.26)$$

If we now evaluate  $K(x, -i\beta\hbar; x, 0)$  we get

$$K(x, -i\beta\hbar; x, 0) = \exp \left[ -\frac{m\omega}{\hbar} \frac{2x^2 (\cosh(\beta\hbar\omega) - 1)}{\sinh(\beta\hbar\omega)} \right] \sqrt{\frac{m\omega}{2\pi\hbar \sinh(\beta\hbar\omega)}} \quad (16.27)$$

$$= \exp \left[ -\frac{m\omega}{\hbar} \tanh \left( \frac{\beta\hbar\omega}{2} \right) x^2 \right] \sqrt{\frac{m\omega}{2\pi\hbar \sinh(\beta\hbar\omega)}}, \quad (16.28)$$

where we have made our lives a bit easier by using a hyperbolic trig identity. If we now perform the  $x$  integral, we see that

$$\int_{-\infty}^{\infty} dx K(x, -i\beta\hbar; x, 0) = \sqrt{\frac{m\omega}{2\pi\hbar \sinh(\beta\hbar\omega)}} \sqrt{\frac{\pi\hbar}{m\omega \tanh \left( \frac{\beta\hbar\omega}{2} \right)}} \quad (16.29)$$

$$= \frac{1}{2 \sinh \left( \frac{\beta\hbar\omega}{2} \right)} \quad (16.30)$$

$$= \sum_{n=0}^{\infty} e^{-\beta\hbar\omega(n+1/2)}. \quad (16.31)$$

We have recovered the thermal partition function of the harmonic oscillator, as promised.

Let's observe that when we go from real to imaginary time, the Euclidean coordinate  $t_E$  parametrizes a circle of size  $\beta\hbar$ . That is, the new coordinate is periodic. Let us write now

$$K(x, t_E = \beta\hbar; x, 0) = \langle x, t_E = \beta\hbar | x, 0 \rangle. \quad (16.32)$$

But since we are working on a circle, it follows that

$$\langle x, t_E = \beta\hbar | = (|x, 0 \rangle)^\dagger \quad (16.33)$$

<sup>74</sup>In relativity language, our metric now has signature  $+, +, +, +$ .

<sup>75</sup>We have expanded  $x[t]$  as an analytic function of  $t$  and analytically continued to the complex plane. Hence the arrow, rather than the equals sign.

if we now identify  $t_E = 0$  and  $t_E = \beta\hbar$ .<sup>76</sup> Moreover, if we now cut this circle in half, we get two copies of the original  $\langle |$  and  $| \rangle$  states. In particular each half is the thermofield double state  $|\text{TFD}\rangle$ , such that

$$|\text{TFD}\rangle = \sum_{n=0}^{\infty} e^{-\beta E_n/2} |E_n\rangle \otimes |E_n\rangle, \quad (16.34)$$

and the whole partition function is

$$\langle \text{TFD} | \text{TFD} \rangle = Z(\beta). \quad (16.35)$$

The correspondence here is such that statistical physics relies on real Boltzmann weights, whereas quantum mechanics uses complex weights (phase factors). This is effectively why we can translate between the two by analytically continuing to imaginary time.

Lecture 17.

**Thursday, November 21, 2019**

Today we'll discuss perturbation theory. This topic will be covered more fully in the next course Quantum II, but let's conceptually discuss anyway.

Only a handful of problems can be solved exactly in quantum mechanics. For the rest, we often resort to perturbative techniques to study small changes from exact solutions. Consider the *anharmonic oscillator* with Hamiltonian

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2 \hat{x}^2 + \frac{\lambda}{4!} \hat{x}^4. \quad (17.1)$$

This Hamiltonian has a symmetry  $\hat{x} \rightarrow -\hat{x}$ , but for arbitrary  $\lambda$  there is no general closed-form solution. However, if  $\lambda \ll 1$  (that is, it is much smaller than the energy levels  $\hbar\omega$  in the problem) then we can use perturbation theory to study the corrections in powers of  $\lambda$ . We write

$$\hat{H} = \hat{H}_0 + \delta\hat{H}_\lambda, \quad (17.2)$$

and we compute expectation values as

$$\langle A(\lambda) \rangle = \langle A(0) \rangle + \lambda \langle A_1 \rangle + \lambda^2 \langle A_2 \rangle + \dots \quad (17.3)$$

Let us note there is no guarantee these series actually converge to the "true value." In general their radius of convergence is infinitesimally small and these are asymptotic series (that is, they converge as  $\lambda \rightarrow 0$  but not as the powers  $\lambda^n$  go to  $\infty$ ). We can make sense of this with a process called Borel resummation and resurgence, if we are careful.

Well, let us forge ahead anyway and treat our perturbation as small. That is,  $V$  changes just a little bit, so we expect that the shifted oscillator will therefore have a spectrum similar to the original unperturbed oscillator. We've probably seen the formula before that

$$E_n(\lambda) = E_{n,\text{osc}} + \delta E_n(\lambda) \quad (17.4)$$

where the shift is given by

$$\delta E_n(\lambda) = \langle E_n | \delta H | E_n \rangle \quad (17.5)$$

$$= \frac{3\lambda}{4!} \left( \frac{\hbar}{2m\omega} \right)^2 (2n^2 + 2n + 1) + O(\lambda^2). \quad (17.6)$$

We won't yet discuss the shift in the wavefunction because this problem is particularly complicated. Let us observe that the classical equations of motion are

$$\ddot{x} + \omega^2 x + \frac{\lambda}{3!m} x^3 = 0. \quad (17.7)$$

If we suppose that

$$x(t) = x_0(t) + \lambda x_1(t) + \dots \quad (17.8)$$

<sup>76</sup>In an equivalence relation way, if you like.

then collecting terms at order 0 and  $O(\lambda)$  we have

$$\ddot{x}_0(t) + \omega^2 x_0(t) = 0 \quad (17.9)$$

$$\ddot{x}_1(t) + \omega^2 x_1(t) + \frac{1}{3!m} x_0^3(t) = 0. \quad (17.10)$$

The solution for  $x_0$  is sines and cosines. But when we plug this into the second equation, we find that integrating by parts, our solutions actually grow with time. That is,  $x_1(t) \rightarrow \infty$  as  $t \rightarrow \infty$ . This seems totally nonphysical– it would be like setting up a pendulum and seeing the plumbob shoot off to arbitrarily large heights.

What's gone wrong? It turns out we cannot trust the asymptotic time behavior of the first-order perturbed wavefunction. If we think of the perturbation as a driving force, there are in fact resonances because of the special spacing of the energy levels of the quantum harmonic oscillator. To solve this properly, we have to keep corrections to all orders and resum [sic] the series to find the actual asymptotic behavior.

Moreover, we should not trust perturbation theory at large energies because the characteristic energy of the oscillator may now be comparable to the perturbation. Nevertheless, even though the wavefunctions are hard to compute correctly, the energy corrections do work in perturbation theory, at least for the first few excited states.

We can also compute so-called *correlation functions*, i.e. expectation values of the form

$$\langle \hat{x}(t_1) \hat{x}(t_2) \hat{x}(t_3) \dots \hat{x}(t_n) \rangle = \text{Tr}(\rho \hat{x}(t_1) \dots \hat{x}(t_n)). \quad (17.11)$$

That is, we compare the values of  $\hat{x}$  at different points in time. Here,  $\hat{x}(t)$  is the Heisenberg operator

$$\hat{x}(t) = U^\dagger(t, t_0) \hat{x}(t_0) U(t, t_0). \quad (17.12)$$

We could also measure time-ordered correlators where  $t_1 > t_2 > t_3 \dots > t_{n-1} > t_n$ . There are other such correlators we could compute– if time ordering doesn't apply, we call these out-of-time-ordered correlators (OTOC), which have been of interest lately because they have been proposed as a measure of quantum chaos.

Consider again the path integral representation, and let  $A$  be some operator whose correlation functions we want to obtain. That is, let us write

$$Z[J] = \int [\mathcal{D}x] e^{\frac{i}{\hbar} S[x] + i \int dt J(t) A(t)}, \quad (17.13)$$

where we have now included a source term  $J$ . That is,  $J(t)$  is now a classical function we get to pick. It turns on and off our operator  $A(t)$ . The correlation functions  $A(t_1)A(t_2)$  are therefore given by

$$\langle A(t_1) A(t_2) \rangle = \frac{\int [\mathcal{D}x] A(t_1) A(t_2) e^{\frac{i}{\hbar} S[x]}}{\int [\mathcal{D}x] e^{\frac{i}{\hbar} S[x]}}. \quad (17.14)$$

That is, we compute expectation values in the same way as statistical mechanics. It's just that our weights are now pure phase. In particular, if we could compute  $Z[J]$  exactly, we claim that we can get expectation values by differentiating the partition function. For notice that

$$\langle A(t_1) A(t_2) \rangle = \frac{1}{Z[J]} \frac{\delta^2 Z[J]}{i^2 \delta J(t_1) \delta J(t_2)} \Big|_{J=0}. \quad (17.15)$$

This generalizes exactly to the quantum field theory case, where our operators are some fields and we can compute their correlation functions in coordinate space or perhaps momentum space, if we prefer.<sup>77</sup>

Since  $Z[J]$  nicely gives us correlation functions, we shall call  $Z[J]$  the generating function of correlators. Let's now find the generating function for the oscillator. The action is

$$S_{\text{osc}} = \frac{1}{2} \int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} dt' x(t') D(t', t) x(t) \quad (17.16)$$

where

$$D(t', t) = m \left( \frac{\partial}{\partial t'} \frac{\partial}{\partial t} - \omega^2 \right) \delta(t - t'). \quad (17.17)$$

<sup>77</sup>See my QFT notes for more on this.

That is, we've just rewritten the oscillator Lagrangian in a funny way by breaking up the  $t$  derivatives. Why did we do this? It makes our path integral look very much like a Gaussian. Hence

$$Z_{\text{osc}}[J] = \int [\mathcal{D}x] \exp \left[ \frac{im}{2\hbar} \int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} dt' x(t') D(t', t) x(t) + \frac{i}{\hbar} \int_{-\infty}^{\infty} dt x(t) J(t) \right]. \quad (17.18)$$

We've chosen  $x(t)$  as the operator we're interested in. This is, morally speaking, just a Gaussian with a shift. Hence we can do it with our formula from before. Up to normalization, it is just

$$Z[J] \propto \frac{1}{\sqrt{\det(D(t', t))}} \exp \left( -\frac{1}{2m\hbar} \int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} dt' J(t') D^{-1}(t', t) J(t) \right). \quad (17.19)$$

These are really the continuous limit of integrals of matrices if we discretized time. That is,  $D(t', t)$  is like a matrix  $D_{ij}$  and the Gaussian term is like  $D_{ij} x_i x_j$ . Similarly, the  $x(t)J(t)$  term becomes a dot product  $x_i J_i$ . If the continuous language makes you uncomfortable, think of these as discrete matrix sums and take the continuous limit.

So we're done. But there's a nice trick we can now use. Our operator  $D$  takes a simple form in momentum space.

$$D(t', t) = m \int_{-\infty}^{\infty} \frac{dv}{2\pi} (v^2 - \omega^2) e^{iv(t-t')}, \quad (17.20)$$

so that

$$D^{-1}(t', t) = G_F(t', t) = -\frac{1}{2\pi m} \int_{-\infty}^{\infty} dv \frac{e^{iv(t-t')}}{v^2 - \omega^2 + i\epsilon}. \quad (17.21)$$

The  $i\epsilon$  is to help us when we integrate.<sup>78</sup>

The harmonic oscillator generating function can be used to set up perturbation theory. Suppose we want to compute

$$\langle \hat{x}(t_1) \hat{x}(t_2) \rangle \quad (17.22)$$

in the anharmonic oscillator. By our definition, this correlation function is given by

$$\langle \hat{x}(t_1) \hat{x}(t_2) \rangle \propto \int [\mathcal{D}x] x(t_1) x(t_2) e^{\frac{i}{\hbar} S_{\text{osc}} - \frac{i}{\hbar} \int \frac{\lambda}{4!} x^4(t) dt} \quad (17.23)$$

$$\simeq \int [\mathcal{D}x] x(t_1) x(t_2) \left( 1 - \frac{\lambda}{4!} \frac{i}{\hbar} \int dt x^4(t) + O(\lambda^2) \right) e^{\frac{i}{\hbar} S_{\text{osc}}}. \quad (17.24)$$

That is, we can now expand the second term in the exponential in powers of  $\lambda$  so that our correlation functions are in fact

$$\langle x(t_1) x(t_2) \rangle_{\text{an}} = \langle x(t_1) x(t_2) \rangle_{\text{osc}} + c\lambda \left\langle x(t_1) x(t_2) \int x^4(t) dt \right\rangle + O(\lambda^2). \quad (17.25)$$

What are these correlation values telling us? Well, we measure  $x$  at some time  $t_2$ , we wait a little while, and then we measure  $x$  again. This looks like a line. The next correction now looks like starting at  $t_2$ , propagating to some point  $t$ , and then measuring again at  $t_1$ . But at  $t$  there are *four*  $x$ s. That is, the order  $\lambda$  term has an  $x^4(t)$ , so we can split into four  $x$ s here. That is, we have a line (propagator) and a vertex joining four legs.

Therefore Feynman diagrams are nothing but a graphical encoding of a Taylor series expansion. These are useful because we can either try to work out the terms in the Taylor expansion up to say order  $\lambda^5$  (including their prefactors), or we can simply draw all the pictures with five vertices and compute the corresponding integrals.

We've spent the last hour arguing that perturbation theory is useful (and ubiquitous). But it's not all there is. Let us now discuss *non-perturbative effects*. For instance, take the double-well potential

$$V(x) = V_0^2 (x^2 - a^2)^2. \quad (17.26)$$

This potential has two wells at  $x = \pm a$ . The classical ground states are a particle sitting in one of the two wells. That is, the potential has a reflection  $x \rightarrow -x$  symmetry ( $\mathbb{Z}_2$ ) but this symmetry is broken by the classical ground states, which correspond to some  $|0, a\rangle, |0, -a\rangle$ . In quantum mechanics, we know that 1D potentials don't admit degenerate eigenstates. The resolution is this. Quantum particles can tunnel

<sup>78</sup>Technically, this is a contour integral. The so-called  $i\epsilon$  prescription tells us how to push the poles at  $v = \pm\omega$ .

through the barrier. The real ground state must be a symmetric combination of the two classical ground states. After normalization, it is

$$E_0 : \frac{1}{\sqrt{2}}(|0, a\rangle + |0, -a\rangle) \quad (17.27)$$

and the next excited state is the antisymmetric combination

$$E_1 : \frac{1}{\sqrt{2}}(|0, a\rangle - |0, -a\rangle). \quad (17.28)$$

What is the energy splitting? It is

$$E_0 = \frac{1}{2}\hbar\sqrt{V''(a)} - \#e^{-S_{\text{tun}}/\hbar} \quad (17.29)$$

$$E_1 = \frac{1}{2}\hbar\sqrt{V''(a)} + \#e^{-S_{\text{tun}}/\hbar}. \quad (17.30)$$

Here,  $S_{\text{tun}}$  is the action corresponding to tunneling. What's notable about this is that the corrections have no expansion about  $\hbar \rightarrow 0$ . This is a non-perturbative effect, as the quantum ground state restores the symmetry. The tunneling trajectory can be mediated by a Euclidean solution (imaginary time), modeled by something called an instanton. The potential flips and it gives us

$$x(t_E) = a \tanh\left(\sqrt{\frac{2}{m}}V_0 a t_E\right). \quad (17.31)$$

These trajectories are new stationary points of the Euclidean action apart from the standard ones we had sitting in the original ground states of the double well.

Lecture 18.

**Tuesday, November 26, 2019**

The path integral has a classical limit,  $\hbar \rightarrow 0$ . That is,

$$\int [\mathcal{D}x] e^{iS[x]/\hbar} \approx e^{iS_{\text{cl}}[x]/\hbar} \sqrt{\frac{2\pi i\hbar}{\det(\delta^2 S[x_{\text{cl}}])}}. \quad (18.1)$$

We can understand this by recognizing that if we expand the action around the classical path, we get

$$S[x] = S[x_{\text{cl}}] + \delta^2 S[x_{\text{cl}}](x - x_{\text{cl}})^2, \quad (18.2)$$

since the first variation of the action vanishes by the classical equations of motion,  $\delta S[x_{\text{cl}}] = 0$ . Hence the integral is the action evaluated on the classical path times what is approximately a Gaussian integral in terms of  $(x - x_{\text{cl}})$ . Away from extremal points, the phase in  $e^{iS[x]/\hbar}$  will oscillate rapidly, so nearby paths will cancel out. This is an example of a stationary phase approximation, or more generally the technique of saddle-point approximation of integrals.

**Double-well and symmetry breaking** Recall that we introduced the double-well potential

$$V(x) = (x^2 - a^2)^2 V_0^2. \quad (18.3)$$

We suggested that the ground states  $|0, -a\rangle, |0, +a\rangle$  were degenerate classically but the quantum ground state was given by

$$\frac{1}{\sqrt{2}}(|0, -a\rangle + |0, +a\rangle) \quad (18.4)$$

with

$$E_+ = \frac{1}{2} \frac{\hbar V_0}{\sqrt{m}} - e^{-\frac{1}{\hbar} S_{\text{tun}}} C. \quad (18.5)$$

We said that the corrections are non-perturbative in  $\hbar$ , but it still remains to find the tunneling amplitude  $S_{\text{tun}}$ .

To warm up, what are the amplitudes

$$A_{\text{cl}} = \langle 0, \pm a | e^{-\hat{H}T/\hbar} | 0, \pm a \rangle \quad (18.6)$$

$$A_{\text{tun}} = \langle 0, -a | e^{-\hat{H}t/\hbar} | 0, +a \rangle, \quad (18.7)$$

where we have defined the classical and tunneling amplitudes? Note that the operator in between is not quite our unitary time operator— for one, it's not even unitary. We've analytically continued to  $T = it$ , if you like. But we'll see that these *Euclidean transition amplitudes* have a sensible interpretation. We can compute them by

$$\int [\mathcal{D}x] e^{-S_E[x]/\hbar}, \quad (18.8)$$

where the Euclidean action is

$$S_E[x] = \int dt_E \left( \frac{m}{2} \left( \frac{dx}{dt_E} \right)^2 + V(x) \right). \quad (18.9)$$

Note the sign flip on  $V(x)$ — this comes from the fact we analytically continued, so time derivatives pick up factors of  $i$ .

For the Euclidean path integral, the saddle-point approximation is easier to motivate because the integrand is exponentially damped for  $\hbar \rightarrow 0$ . So a (real) Gaussian is a good approximation:

$$\int [\mathcal{D}x] e^{-S_E[x]} \approx e^{-S_E[x_{\text{cl}}]} \sqrt{\frac{2\pi\hbar}{\det(\delta^2 S_E[x_{\text{cl}}])}}. \quad (18.10)$$

Notice that the amplitude  $A_{\text{cl}}$  gets contributions from  $x_{\text{cl}}^E(T_E) = \text{constant}$ . That is,

$$\langle 0, -a | e^{-\hat{H}t/\hbar} | 0, -a \rangle \quad (18.11)$$

is dominated by

$$x_{\text{cl}}^E(t_E) = -a, \quad (18.12)$$

and so the numerical answer will depend on the  $\delta^2 S$  corrections. The amplitude for  $\langle 0, +a | e^{-\hat{H}t/\hbar} | 0, +a \rangle$  is similar.

But  $A_{\text{tun}}$  is different. Let us ask what the Euclidean solution is. Now

$$x(-T/2) = -a, \quad x(T/2) = a, \quad (18.13)$$

corresponding to the particle starting in one well (say, the left one) and ending up in the other well (the right one) at a time  $T$  later. From Euler-Lagrange ( $\delta S_E = 0$ ) we can write the equation of motion,

$$m \frac{d^2 x}{dt_E^2} = -V'(x) \quad (18.14)$$

or equivalently

$$m \left( \frac{dx}{dt_E} \right)^2 - V(x) = 0. \quad (18.15)$$

We claimed last time that

$$x_{\text{cl}}^E(t_E) = a \tanh \left( 2\sqrt{\frac{2}{m}} V_0 a t_E \right). \quad (18.16)$$

This has the right limiting behavior:

$$x_{\text{cl}}^E(-T/2) \xrightarrow{T \rightarrow \infty} -a \quad (18.17)$$

$$x_{\text{cl}}^E(+T/2) \xrightarrow{T \rightarrow \infty} +a \quad (18.18)$$

and we see that most of the action (in the informal sense) is located around  $t_E = 0$  in a small interval. This solution is known as the *instanton* because it takes only an instant. We can do more, actually.

$$A_{\text{tun}} = \exp\left(-\frac{1}{\hbar} S_E[x_{\text{cl}}^E]\right) \times \sqrt{\frac{2\pi\hbar}{\det(\delta^2 S_E)}} \quad (18.19)$$

$$\sim C \exp\left(-\frac{1}{\hbar} \int_{-a}^a dx \sqrt{2mV(x)}\right) \quad (18.20)$$

$$= C e^{-S_{\text{tun}}/\hbar}. \quad (18.21)$$

where we've used the equation of motion

$$m \left( \frac{dx}{dt_E} \right)^2 - V(x) = 0 \quad (18.22)$$

for  $x = x_{\text{cl}}^E$ . That is,

$$S_E = \int_{-T/2}^{T/2} dt_E 2V(x) \quad (18.23)$$

with

$$\frac{dx}{dt_E} = \sqrt{\frac{V(x)}{m}}. \quad (18.24)$$

Our instanton solution is a special solution which is a saddle point of the Euclidean action; they look quantum in real time but classical in imaginary time. The rotation to imaginary time has helped us to find a classical trajectory that therefore had the interpretation of quantum tunneling in real time.<sup>79</sup>

We notice that the energy shift has no expansion in  $\hbar$ . This is very strange— we're used to thinking of the  $\hbar \rightarrow 0$  limit as the classical limit, but we cannot write down any of the corrections in  $\hbar$  for the term

$$e^{-\frac{1}{\hbar} S_{\text{tun}}} C. \quad (18.25)$$

We also see that tunneling means that there is no symmetry-breaking in 1D quantum mechanics. Finally, note that this integral over  $\sqrt{2mV(x)}$  will appear again next quarter as part of the WKB approximation; WKB is often used for tunneling calculations.

**Symmetries** In physics, symmetries are statements of invariance. We change the system in some way (e.g. rotate a sphere), but nothing happened as a result of our change. Symmetries are particularly useful to us for two reasons— one, they constrain the states allowed in the system, and two, they (in the continuous case) provide us with conserved quantities and therefore constrain the transitions between states.

For some symmetry

$$|\psi\rangle \rightarrow S|\psi\rangle, \quad (18.26)$$

Wigner's theorem states that the symmetry  $S$  is a unitary operator,  $S^\dagger S = \mathbb{I}$ , with one caveat we'll revisit later. Look at the transformation of  $\hat{H}$ :

$$\hat{H} \rightarrow S^\dagger \hat{H} S. \quad (18.27)$$

The statement of invariance is that

$$\hat{H} = S^\dagger \hat{H} S, \quad (18.28)$$

i.e. the Hamiltonian is unchanged under conjugation by some unitary  $S$ .

Symmetries can be discrete or continuous. A reflection symmetry is the classic example of a discrete symmetry— flip and flip back. Parity and time-reversal are two important discrete symmetries. A rotation symmetry, on the other hand, is usually parametrized by an angle, so it is continuous. Translations are similar.

For a continuous symmetry transformation depending on  $\lambda$ , we can expand about small  $\lambda$  as

$$S(\lambda) = \mathbb{I} - i\lambda \hat{s} + O(\lambda^2) \quad (18.29)$$

with

$$\hat{s}^\dagger = s \quad (18.30)$$

<sup>79</sup>Note that some problems don't have good classical interpretations when we analytically continue. Most tunneling problems will have this nice interpretation, but questions of entanglement or superposition generally won't.

a Hermitian operator. If  $S$  is a symmetry, we find that

$$[\hat{H}, \hat{s}] = 0, \quad (18.31)$$

which by the Heisenberg equations of motion says that

$$\frac{d\hat{s}}{dt} = [\hat{H}, \hat{s}] = 0, \quad (18.32)$$

i.e.  $\hat{s}$  is time-independent.

Symmetries in physics form *groups*.

**Definition 18.33.** Groups are sets of elements  $G$  equipped with a binary operation  $*$  such that for any two elements  $a, b \in G$ , their product  $a * b \in G$  is also an element of the group. There exists an identity element  $1$  such that  $1 * a = a \forall a$ , and an inverse to every element  $a^{-1}$  such that  $a^{-1} * a = 1$ . The operation  $*$  is also associative.

In physics, it is often useful to look at infinitesimal elements of continuous (Lie) groups around the identity. The generators of these infinitesimal transformations are not elements of the group; they are elements of an algebra (a set equipped with a bracket rule  $[\cdot, \cdot]$ ).

For every symmetry generator we have an operator that commutes with the Hamiltonian, which means we can simultaneously diagonalize  $\hat{H}$  and the symmetry generators, up to the commutation rules of the symmetry generators.

For two symmetry generators  $\hat{s}_1, \hat{s}_2$ , we have

$$[\hat{H}, \hat{s}_1] = 0 = [\hat{H}, \hat{s}_2] \quad (18.34)$$

but in general

$$[\hat{s}_1, \hat{s}_2] \neq 0. \quad (18.35)$$

If the group multiplication is commutative we say the group is *abelian*, and therefore the generators also commute. But many important groups are nonabelian and have nontrivial commutation relations between their generators. For instance, the spin algebra has three generators  $\sigma_1, \sigma_2, \sigma_3$ , such that

$$[\sigma_i, \sigma_j] = 2i\epsilon_{ijk}\sigma_k, \quad i = 1, 2, 3. \quad (18.36)$$

Aside: how do we know when we've got all the symmetries? Degeneracies are usually an indication of a symmetry, as we saw in a previous homework. One thing we can do is try to close the algebra by computing brackets of the generators we have in hand. If we get elements we already know about, we're done, but if we get new elements, then there are more symmetries.<sup>80</sup>

**Parity and time-reversal** The parity symmetry takes the form

$$x \rightarrow -x \quad (18.37)$$

in 1D, and it is

$$(x, y, z) \rightarrow (-x, -y, -z) \quad (18.38)$$

in 3D. This is a discrete symmetry, and its application twice is the identity  $\mathbb{I}$ .

The time-reversal symmetry, on the other hand, is a bit more subtle. We would like to have

$$t \rightarrow -t, \quad (18.39)$$

but this can't quite work in the Schrödinger equation because

$$i\frac{\partial\psi(x, t)}{\partial t} = \hat{H}\psi(x, t). \quad (18.40)$$

Just flipping the sign in  $t$  wouldn't work, since it would change the sign on the LHS of the equation. Hence we need to actually write

$$\psi(x, t) \rightarrow \psi^*(x, -t) \quad (18.41)$$

and include a complex conjugation.

We can see that parity is implemented by a linear unitary  $P$  such that

$$P\hat{x} + \hat{x}P = \{\hat{x}, P\} = 0, \quad (18.42)$$

<sup>80</sup>This is a lot like finding Killing vectors in relativity.

while time reversal is described by an antilinear, anti-unitary transformation  $T$ .

Lecture 19.

**Tuesday, December 3, 2019**

*Note.* Today is Sean's first guest lecture, as Mukund is away at a conference.

**Symmetries in QM** In classical mechanics, we had a Lagrangian  $\mathcal{L}(q_i, \dot{q}_i, t)$  which depended on some coordinates, their first time derivatives, and perhaps time itself. Symmetries in classical mechanics were then described by coordinate transformations  $q_i \rightarrow q_i + \delta q_i$  such that  $\delta\mathcal{L} = \frac{\partial\mathcal{L}}{\partial q_i} \delta q_i = 0$ , which resulted in conserved currents by the Noether procedure. This generalizes to quantum mechanics as Ehrenfest's theorem, which says that classical equations of motion hold on the level of expectation values (see our previous discussions).

We'll describe symmetries in QM with some different language, though.

**Definition 19.1.** A symmetry operator  $S$  is a unitary operator  $SS^\dagger = \mathbb{I}$  such that states transform as

$$|\psi\rangle \rightarrow S|\psi\rangle, \quad \rho \rightarrow S\rho S^\dagger. \quad (19.2)$$

We say that  $S$  is a symmetry if

$$\hat{H} = S^\dagger \hat{H} S. \quad (19.3)$$

Note that while we should be careful for general operators to put the  $S^\dagger$  on the left, for Hermitian operators it will not matter because we can just take the dagger of the entire expression (i.e.  $\hat{H} = \hat{H}^\dagger = S\hat{H}^\dagger S^\dagger = S\hat{H}S^\dagger$ ).

We introduced groups last time. A group  $G$  is a set of elements  $\{x_i\}$  equipped with a binary operation  $*$  such that  $\forall x, y \in G$ ,

- the product  $x * y$  is in  $G$
- there exists an identity  $e$  such that  $e * x = x * e = x$
- the operation is associative,  $x * (y * z) = (x * y) * z$
- there exists an inverse  $x^{-1}$  for each element  $x$  such that  $x^{-1} * x = e$ .

Some examples include  $SO(2) = \left\{ \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix}, 0 \leq \theta < 2\pi \right\}$ , which is the continuous group of (real) rotations in 2 dimensions. We could also look at discrete groups like  $\mathbb{Z}_2 = \{\pm 1\}$ , where the group operation is multiplication.

In the case of continuous groups, we can expand group elements in terms of a small real parameter,

$$S = \mathbb{I} - i\lambda \hat{S} + O(\lambda^2). \quad (19.4)$$

If  $S$  is unitary, then the operator  $\hat{S}$  is Hermitian. The prototypical example is unitary time evolution,

$$U = e^{-\frac{i}{\hbar} \hat{H} t} = \mathbb{I} - \frac{i}{\hbar} t \hat{H}. \quad (19.5)$$

In particular, if  $S$  is a symmetry of the system, then

$$\hat{H} = S^\dagger \hat{H} S \quad (19.6)$$

$$= (\mathbb{I} + i\lambda \hat{S}) \hat{H} (\mathbb{I} - i\lambda \hat{S}) \quad (19.7)$$

$$= \hat{H} - i\lambda (\hat{S} \hat{H} - \hat{H} \hat{S}) + O(\lambda^2), \quad (19.8)$$

which tells us that

$$[\hat{S}, \hat{H}] = 0. \quad (19.9)$$

Suppose we now have a Hamiltonian  $\hat{H}$  with some degenerate energy eigenstates

$$\{|E_{n,i}\rangle, i = 1, \dots, n\}, \quad (19.10)$$

such that

$$\hat{H}|E_{n,i}\rangle = E_n|E_{n,i}\rangle. \quad (19.11)$$

Then we can lift the degeneracy by acting with our symmetry operator  $\hat{S}$  on these eigenstates and measuring the eigenvalues of  $\hat{S}$ . That is,

$$\hat{S}|E_{n,i}\rangle = S_i|E_{n,i}\rangle. \quad (19.12)$$

**Lemma 19.13** (Schur's lemma). *Any operator that commutes with all operators of an irreducible representation acting on a Hilbert space must be a multiple of the identity.*

That is, we think of this set of eigenstates as its own Hilbert space. Then  $\hat{H}$  commutes with  $\hat{S}$ , so it is a multiple of the identity.

**Representation theory** Representation theory is the statement of assigning linear maps (operators) to elements of groups acting on some vector space. That is, we have a Hilbert space  $\mathcal{H}$  and a symmetry group  $G$ . Then the action of a symmetry  $S$  acting on vectors in the Hilbert space is as follows:

$$S|\psi\rangle = e^{i\lambda\hat{S}}|\psi\rangle. \quad (19.14)$$

That is, we exponentiate elements  $\hat{S}$  of the Lie algebra to get elements  $S$  of the Lie group.

Let us make this concrete. Two of the most important symmetries in quantum mechanics are parity and time reversal.<sup>81</sup> The parity symmetry corresponds to a Hermitian operator  $P$  such that  $|\psi\rangle \rightarrow P|\psi\rangle$  where

$$\langle\psi|P^\dagger\hat{x}P|\psi\rangle = -\langle\psi|\hat{x}|\psi\rangle. \quad (19.15)$$

That is, it flips the expectation values of  $\hat{x}$ . Hence

$$P^\dagger\hat{x}P = -\hat{x} \implies \{\hat{x}, P\} = 0. \quad (19.16)$$

We should note that parity is also unitary, i.e.  $P^\dagger P = \mathbb{I}$ . As parity flips space, it also anticommutes with momentum, and it commutes with angular momentum,<sup>82</sup> i.e.

$$\{P, \hat{p}\} = 0 \quad (19.17)$$

but also

$$\mathbf{L} = \hat{x} \times \hat{p}, \quad [\mathbf{L}, P] = 0 \quad (19.18)$$

As we stated earlier,  $P$  is a symmetry of a system (it is parity-invariant) if

$$[\hat{H}, P] = 0. \quad (19.19)$$

Equivalently,

$$V(\hat{x}) = V(-\hat{x}) \quad (19.20)$$

since  $P$  automatically commutes with the  $p^2$  kinetic term. Notice that

$$\hat{x}P|x\rangle = -P\hat{x}|x\rangle = -xP|x\rangle, \quad (19.21)$$

which tells us that  $P|x\rangle$  is an eigenvector of  $\hat{x}$  with eigenvalue  $-x$ . Hence

$$P|x\rangle = e^{i\theta_p}|-x\rangle, \quad (19.22)$$

i.e.  $P|x\rangle$  is proportional to  $|-x\rangle$ . If we choose  $\theta_p = 0$  we see that

$$P^2|x\rangle = |x\rangle. \quad (19.23)$$

This in turn tells us that the eigenvalues of  $P$  are  $\pm 1$ . Hence we can also describe the action of  $P$  on a wavefunction as

$$\psi(-x) = \langle x|P|\psi\rangle = \pm\langle x|\psi\rangle = \pm\psi(x). \quad (19.24)$$

Hence if  $|\psi\rangle$  is an eigenket of  $P$ , then  $\psi(x) = \pm\psi(-x)$ .

<sup>81</sup>These are  $\mathbb{Z}_2$  symmetries, in the sense that doing them twice is the identity.

<sup>82</sup>This is because angular momentum is classically a pseudovector, not a vector.

**Selection sectors** Suppose that  $|\psi_1\rangle, |\psi_2\rangle$  are vectors in a Hilbert space  $\mathcal{H}$  such that for all (Hermitian) operators  $A$ ,

$$\langle \psi_1 | A | \psi_2 \rangle = 0. \quad (19.25)$$

This implies that  $|\psi_1\rangle, |\psi_2\rangle$  live in different *selection sectors* of the Hilbert space  $\mathcal{H}$ . As an example, consider

$$P|\psi_1\rangle = \epsilon_1|\psi_1\rangle, P|\psi_2\rangle = \epsilon_2|\psi_2\rangle. \quad (19.26)$$

Then

$$\langle \psi_2 | \psi_1 \rangle = 0 \text{ if } \epsilon_1 \neq \epsilon_2. \quad (19.27)$$

More generally

$$\langle \psi_2 | A | \psi_1 \rangle = \begin{cases} 0 & \text{unless } \epsilon_1 = -\epsilon_2 \text{ and } \{P, A\} = 0 \\ 0 & \text{unless } \epsilon_1 = +\epsilon_2 \text{ and } [P, A] = 0. \end{cases} \quad (19.28)$$

That is, there is no way to get between these two operators, and their overlap is zero (since the identity is certainly hermitian).

**Time reversal** Time-reversal symmetry is, morally speaking, the symmetry  $t \rightarrow -t$ . The actual implementation is a little more complicated, though. The original Schrödinger's equation says

$$i\hbar\partial_t\psi(x, t) = \hat{H}\psi(x, t), \quad (19.29)$$

so under the transformation  $t \rightarrow -t, \psi(x, t) \rightarrow \psi^*(x, -t)$ , we see that the equation becomes

$$(i\hbar\partial_{-t}\psi(x, -t))^* = (\hat{H}\psi(x, -t))^* \implies i\hbar\partial_t\psi^*(x, -t) = \hat{H}\psi^*(x, -t). \quad (19.30)$$

So  $\psi^*(x, -t)$  is also a solution.

Time-reversal is also a bit subtle because it is *anti-unitary*, i.e. if

$$|\psi_1\rangle \mapsto |\tilde{\psi}_1\rangle = U_a|\psi_1\rangle, \quad |\psi_2\rangle \mapsto |\tilde{\psi}_2\rangle = U_a|\psi_2\rangle, \quad (19.31)$$

then it is anti-unitary,

$$\langle \tilde{\psi}_1 | \tilde{\psi}_2 \rangle = \langle \psi_1 | \psi_2 \rangle^* \quad (19.32)$$

and also anti-linear,

$$U_a(\alpha|\psi\rangle) = \alpha^*U_a|\psi\rangle \text{ for } \alpha \in \mathbb{C}. \quad (19.33)$$

In general such operators can be written as  $U_a = UC$ , the product of a unitary operator and complex conjugation.

Now let us actually implement time reversal as follows. In the Schrödinger picture, states evolve as

$$|\psi(t)\rangle = U(t, 0)|\psi(0)\rangle = e^{-i\hat{H}t}|\psi(0)\rangle, \quad (19.34)$$

so then we want time reversal to act in the following way:

$$e^{-i\hat{H}t}T|\psi\rangle = Te^{i\hat{H}t}|\psi\rangle. \quad (19.35)$$

That is, evolving backwards in time and then performing time reversal should be equivalent to performing time reversal first and then evolving forwards in time. Infinitesimally, it follows that

$$-i\hat{H}T|\psi\rangle = -iT\hat{H}|\psi\rangle \implies [T, \hat{H}] = 0. \quad (19.36)$$

One can then show that time reversal acts in the following way:

$$\langle \psi_1 | A | \psi_2 \rangle = \langle \tilde{\psi}_2 | TA^\dagger T^{-1} | \tilde{\psi}_1 \rangle, \quad (19.37)$$

which is left as an exercise. If  $A$  is Hermitian, then

$$\langle \psi_1 | A | \psi_2 \rangle = \langle \tilde{\psi}_1 | TAT^{-1} | \tilde{\psi}_1 \rangle \implies TAT^{-1} = \pm A. \quad (19.38)$$

Finally, we can describe the impact on eigenstates of position and momentum:

$$|p\rangle \rightarrow T|p\rangle = e^{i\theta_T}|-p\rangle \quad (19.39)$$

$$|x\rangle \rightarrow T|x\rangle = |x\rangle. \quad (19.40)$$

Lecture 20.

**Thursday, December 5, 2019**

*Note.* Today is Sean's second guest lecture, and the final lecture of the course.

Today we'll discuss more about continuous symmetries. Notice that for a translation

$$\psi(x) \rightarrow \psi(x+a), \quad a \in \mathbb{R}, \quad (20.1)$$

we can express this infinitesimally as

$$\psi(x) \rightarrow \psi(x+\epsilon) = \psi(x) + \epsilon \frac{\partial \psi}{\partial x} + O(\epsilon^2) \quad (20.2)$$

$$= \left(1 + \epsilon \frac{\partial}{\partial x}\right) \psi(x), \quad (20.3)$$

where we recognize the derivative as related to the momentum operator. Namely, these are the first terms in the expansion of  $e^{-i\epsilon \hat{p}}$  (maybe up to some factors of  $\hbar$ ).

Similarly, we know the classical angular momentum operator has the form

$$\mathbf{L} = \mathbf{x} \times \mathbf{p}. \quad (20.4)$$

We can construct the angular momentum operators  $\hat{L}_i$  by promoting  $x$  and  $p$  to operators so that component-wise, we get

$$\hat{L}_i = \epsilon_{ijk} \hat{x}_j \hat{p}_k, \quad (20.5)$$

where  $\epsilon_{ijk}$  is the Levi-Cevita symbol. I use the Einstein summation convention that repeated indices are summed over, and the indices  $i, j, k$  run from 1 to 3. Hence

$$[L_i, L_j] = \epsilon_{imn} \epsilon_{jrs} [\hat{x}_m \hat{p}_n, \hat{x}_r \hat{p}_s] \quad (20.6)$$

$$= \epsilon_{imn} \epsilon_{jrs} (\hat{x}_m [\hat{p}_n, \hat{x}_r] \hat{p}_s - \hat{x}_r [\hat{p}_s, \hat{x}_m] \hat{p}_n) \quad (20.7)$$

$$= -i\hbar \epsilon_{imn} \epsilon_{jrs} (\hat{x}_m \hat{p}_s \delta_{nr} - \hat{x}_r \hat{p}_n \delta_{sm}). \quad (20.8)$$

Using the property that  $\epsilon_{ijk} \epsilon_{mnk} = \delta_{im} \delta_{jn} - \delta_{in} \delta_{jm}$ , we can therefore write this commutator as

$$[\hat{L}_i, \hat{L}_j] = -i\hbar (-(\delta_{ij} \delta_{ms} - \delta_{is} \delta_{jm}) \hat{x}_m \hat{p}_s + (\delta_{ij} \delta_{nr} - \delta_{ir} \delta_{jn}) \hat{x}_r \hat{p}_n) \quad (20.9)$$

$$= i\hbar (\hat{x}_i \hat{p}_j - \hat{x}_j \hat{p}_i) \quad (20.10)$$

$$= i\hbar \epsilon_{ijk} L_k. \quad (20.11)$$

Alternately, we can do this using the fact that  $\hat{p}$  is a derivative to explicitly write  $\hat{L}_i = -i\hbar \epsilon_{ijk} x_j \partial_k$ . Now we can exponentiate the angular momentum generators to get a general rotation  $R \in SO(3)$ , which takes the form

$$R = \exp\left(-\frac{i}{\hbar}(\theta_1 \hat{L}_1 + \theta_2 \hat{L}_2 + \theta_3 \hat{L}_3)\right). \quad (20.12)$$

If the Hamiltonian of a system commutes with the rotation generator(s),

$$[\hat{H}, \hat{L}_i] = 0, \quad (20.13)$$

then we say our system has rotational symmetry.

We can also construct something called the quadratic Casimir,

$$L^2 = L_1^2 + L_2^2 + L_3^2. \quad (20.14)$$

The point of constructing this Casimir is that

$$[\hat{L}^2, \hat{L}_i] = 0, \quad (20.15)$$

so it labels states of a definite total angular momentum, as we saw in Schur's lemma last time, and the others will label the states in the subspace.

Since  $\hat{L}^2$  commutes with each of the  $\hat{L}_i$ s, we can pick one of them (conventionally  $L_3$ ) and simultaneously diagonalize  $\hat{L}^2$  and  $\hat{L}_3$ . Let us also define

$$\hat{L}_{\pm} = \hat{L}_1 \pm i\hat{L}_2, \quad (20.16)$$

and notice that

$$\hat{L}_{\pm}^{\dagger} = \hat{L}_{\mp}. \quad (20.17)$$

It's a few lines of algebra to verify the following commutation relations:

$$[\hat{L}_3, \hat{L}_{\pm}] = \pm \hbar \hat{L}_{\pm}, \quad [\hat{L}_+, \hat{L}_-] = 2\hbar \hat{L}_3, \quad [\hat{L}^2, \hat{L}_3] = [\hat{L}^2, \hat{L}_{\pm}] = 0. \quad (20.18)$$

From here, we can already see that these commutation relations are starting to look like the harmonic oscillator– we have raising and lowering operators that commute with the  $\hat{L}^2$  operator and the individual angular momentum operator  $\hat{L}_3$ . Let's get rid of the  $\hbar$ s by defining

$$\hat{L}_i = \hbar \hat{l}_i. \quad (20.19)$$

Then our Hilbert space has states  $|\lambda, \mu\rangle$  such that

$$\hat{l}^2 |\lambda, \mu\rangle = \lambda |\lambda, \mu\rangle, \quad \hat{l}_3 |\lambda, \mu\rangle = \mu |\lambda, \mu\rangle. \quad (20.20)$$

Moreover,

$$\hat{l}_{\pm} |\lambda, \mu\rangle = (\mu \pm 1) \hat{l}_{\pm} |\lambda, \mu\rangle, \quad \hat{l}^2 \hat{l}_{\pm} |\lambda, \mu\rangle = \lambda \hat{l}_{\pm} |\lambda, \mu\rangle. \quad (20.21)$$

Hence we can write

$$\hat{l}_{\pm} |\lambda, \mu\rangle = A_{\pm}(\lambda, \mu) |\lambda, \mu \pm 1\rangle, \quad (20.22)$$

i.e. we have recognized  $\hat{l}_{\pm} |\lambda, \mu\rangle$  as another eigenstate of  $\hat{l}_3$  with eigenvalue  $\mu \pm 1$ . So  $\hat{l}_{\pm}$  really are ladder operators moving us up and down in  $\mu$  eigenvalues. Well, what is this prefactor? Notice that

$$\langle \lambda, \mu | \hat{l}^2 - \hat{l}_3^2 | \lambda, \mu \rangle = \langle \lambda, \mu | \frac{1}{2} (\hat{l}_+ \hat{l}_- + \hat{l}_- \hat{l}_+) | \lambda, \mu \rangle = \langle \lambda, \mu | \hat{l}_1^2 + \hat{l}_2^2 | \lambda, \mu \rangle \geq 0, \quad (20.23)$$

since this last term is manifestly non-negative (it is a sum of two inner products). Evaluating the first expression on the left explicitly, we see that

$$\lambda - \mu^2 \geq 0. \quad (20.24)$$

This tells us that there is some maximum allowed value of  $\mu$ , and also some minimum value of  $\mu$ . We're not required to actually saturate the inequality, but we will prove that the mathematics allows us to do so.

That is, there is a highest  $\mu_{\text{hw}}$  such that

$$\hat{l}_+ |\lambda, \mu_{\text{hw}}\rangle = 0 \quad (20.25)$$

and a lowest  $\mu_{\text{lw}}$  such that

$$\hat{l}_- |\lambda, \mu_{\text{lw}}\rangle = 0. \quad (20.26)$$

We have the anticommutation and commutation relations

$$\{\hat{l}_+, \hat{l}_-\} = 2\hat{l}^2 - 2\hat{l}_3^2, \quad [\hat{l}_+, \hat{l}_-] = 2\hat{l}_3, \quad (20.27)$$

so

$$\hat{l}_- \hat{l}_+ |\lambda, \mu_{\text{hw}}\rangle = (\hat{l}^2 - \hat{l}_3^2 - \hat{l}_3) |\lambda, \mu_{\text{hw}}\rangle = 0, \quad (20.28)$$

which tells us that

$$\lambda = \mu_{\text{hw}}(\mu_{\text{hw}} + 1). \quad (20.29)$$

Similarly

$$\hat{l}_+ \hat{l}_- |\lambda, \mu_{\text{lw}}\rangle = (\hat{l}^2 - \hat{l}_3^2 + \hat{l}_3) |\lambda, \mu_{\text{lw}}\rangle = 0, \quad (20.30)$$

which says that

$$\lambda = \mu_{\text{lw}}(\mu_{\text{lw}} - 1). \quad (20.31)$$

We conclude that

$$\mu_{\text{hw}} = -\mu_{\text{lw}}, \quad (20.32)$$

and moreover

$$\mu_{\text{hw}} - \mu_{\text{lw}} = 2\mu_{\text{hw}} \in \mathbb{Z}_{\geq 0}. \quad (20.33)$$

Let us now call this highest weight

$$j = \mu_{\text{hw}} \in \frac{1}{2}\mathbb{Z}_{\geq 0}. \quad (20.34)$$

That is,  $j$  can be a non-negative integer or half-integer. Now

$$\lambda = j(j+1), \quad (20.35)$$

which tells us that for a given value of  $j$ , there is a  $2j + 1$ -dimensional Hilbert space such that our states can be labeled as

$$|j, m\rangle, \quad m = -j, -j + 1, \dots, j - 1, j. \quad (20.36)$$

Then

$$\hat{L}^2|j, m\rangle = j(j+1)|j, m\rangle, \quad \hat{L}_3|j, m\rangle = m|j, m\rangle. \quad (20.37)$$

The last thing we need to do is find the prefactors  $A_{\pm}(j, m)$ :

$$\hat{L}_{\pm}|j, m\rangle = A_{\pm}(j, m)|j, m \pm 1\rangle. \quad (20.38)$$

Notice that by taking the adjoint of this expression we have

$$\langle j, m|\hat{L}_{\mp} = A_{\pm}^*(j, m)\langle j, m \pm 1|. \quad (20.39)$$

If we now take the inner product, we get

$$\langle j, m|\hat{L}_{\mp}\hat{L}_{\pm}|j, m\rangle = |A_{\pm}(j, m)|^2\langle j, m \pm 1|j \pm 1\rangle = |A_{\pm}(j, m)|^2, \quad (20.40)$$

taking the eigenstates to be normalized. But we can also evaluate the expression on the left explicitly by noticing that

$$\langle j, m|\hat{L}_{\mp}\hat{L}_{\pm}|j, m\rangle = \langle j, m|\hat{L}^2 - \hat{L}_3^2 \mp \hat{L}_3|j, m\rangle = j(j+1) - m^2 \mp m = (j+m)(j-m) + (j \mp m). \quad (20.41)$$

We conclude that

$$A_{\pm}(j, m) = \sqrt{(j \mp m)(j \pm m + 1)}. \quad (20.42)$$

**Superselction sectors** Notice that the values of  $j$  separate our Hilbert space into subspaces labeled by total angular momentum. That is,

$$\mathcal{H} = \bigoplus_j \mathcal{H}_j, \quad (20.43)$$

where  $\mathcal{H}_j$  is the subspace corresponding to all states of total angular momentum  $j$ . The  $L$  operators don't mix states of different  $j$ , and so the Hamiltonian has block diagonal form where each block is a  $(2j+1) \times (2j+1)$  matrix.

A general rotation element  $\mathcal{D}(R)$  is given by

$$\mathcal{D}(R) = e^{-\frac{i}{\hbar}(\hat{n} \cdot \hat{L})\phi}. \quad (20.44)$$

That is, we specify a rotation axis  $\hat{n}$  and an angle  $\phi$  about which to rotate. It has elements

$$\mathcal{D}_{m,m'}^{(j)} = \langle j, m|e^{-\frac{i\phi}{\hbar}\hat{n} \cdot \hat{L}}|j, m'\rangle. \quad (20.45)$$

Then

$$L^2\mathcal{D}(R)|j, m\rangle = \mathcal{D}(R)L^2|j, m\rangle = j(j+1)\hbar^2[\mathcal{D}(R)|j, m\rangle], \quad (20.46)$$

since  $\hat{L}^2$  commutes with all the individual  $\hat{L}_i$ s. That is, performing a rotation doesn't change the overall angular momentum. Now

$$\mathcal{D}(R)|j, m\rangle = \sum_{m'} |j, m'\rangle \langle j, m'|\mathcal{D}(R)|j, m\rangle = \sum_{m'} |j, m'\rangle \mathcal{D}_{m,m'}^{(j)}(R). \quad (20.47)$$

That tells us that the matrix elements of  $\mathcal{D}_{m,m'}^{(j)}(R)$  have the interpretation of transition amplitudes for starting in an  $L_z$  eigenvalue  $m$  state and ending up in an eigenvalue  $m'$  state after performing the rotation  $R$ .

We can write out explicit forms for the angular momentum operators in spherical coordinates. That is, if

$$x = r \sin \theta \cos \phi, \quad y = r \sin \theta \sin \phi, \quad z = r \cos \theta, \quad (20.48)$$

then

$$\hat{L}_3 = -i\frac{\partial}{\partial \phi}, \quad \hat{L}_{\pm} = \pm e^{i\phi} \left( \frac{\partial}{\partial \theta} + i \cot \theta \frac{\partial}{\partial \phi} \right). \quad (20.49)$$

Let us consider the position-space representation of eigenstates  $|j, m\rangle$ . That is,

$$\langle \theta, \phi|j, m\rangle = Y_j^m(\theta, \phi). \quad (20.50)$$

We have

$$\hat{L}_+|j, j\rangle = 0, \quad \hat{L}_3|j, j\rangle = j|j, j\rangle, \quad (20.51)$$

so that in a coordinate basis,

$$e^{i\phi} \left( \frac{\partial}{\partial \theta} + i \cot \theta \frac{\partial}{\partial \phi} \right) Y_j^j(\theta, \phi) = 0, \quad (20.52)$$

$$-i \frac{\partial}{\partial \phi} Y_j^j(\theta, \phi) = j Y_j^j(\theta, \phi). \quad (20.53)$$

If we solve these differential equations, we find that

$$Y_j^j(\theta, \phi) = (-1)^j \sqrt{\frac{(2j+1)!}{4\pi}} \frac{1}{2^j j!} (\sin \theta)^j e^{ij\phi}, \quad (20.54)$$

and to get the remaining harmonics we can just act  $k$  times with  $\hat{L}_-$  to get

$$(\hat{L}_-)^k Y_j^j = Y_j^{j-k} \quad (20.55)$$

or equivalently

$$Y_j^m = \left[ -e^{i\phi} \left( \frac{\partial}{\partial \theta} + i \cot \theta \frac{\partial}{\partial \phi} \right) \right]^{j-m} Y_j^j(\theta, \phi). \quad (20.56)$$
